Qablunaatitut: Physiological response of soft-shell clam (Mya truncata) to spring microalgal blooms (PRECAB)Leads: Lisa Matthes (DFO) and Michelle Kamula (DFO)Dates: May 1, 2025-March 31, 2026Funding: DFO-Coastal Environmental Baseline ProgramThe truncate soft-shell clam Mya truncata is an important subsistence food for Inuit communities across Nunavut. Additionally, the filter feeding clam is an important food source for bearded seals and walruses, providing a significant linkage for energy and nutrient to transfer between primary producers and the higher trophic species. Despite their ecological importance in the Arctic marine food web, their life history and reproductive cycle in relation to the timing of primary production, like sea ice algae and open water phytoplankton, is not well known. This lack of understanding impedes any predictions of the impact of climate and/or anthropogenic related changes on the reproductive potential and ultimately clam biomass available for harvest in the future. The objective of this project is to investigate how the soft-shell clam population of Mya truncata, found in the coastal marine waters near the community of Qikiqtarjuaq, physiologically respond to different microalgal blooms of sea ice algae in spring and phytoplankton in summer. To investigate the clams physiological response to different food sources, we plan to collect sea ice and water samples to investigate microalgal biomass, diversity and fatty acid composition; soft-shell clams will be collected by SCUBA diving to examine food web signatures and gonadal development stages. This investigation will provide more information on which role the different microalgal communities play in the spawning cycle of M. truncata. Where, when, and how long the field research will be:To capture seasonal changes in the gonadal development stages of the soft-shell clams in response to the different microalgal blooms, we plan to sample clams during the ice-covered season 20 May to 6 June, 2025 and over a two week period in July 2025 . Samples will be collected at 3 – 4 coastal stations near the community of Qikiqtarjuaq (see Figure 1). Methods used to conduct the research:In May/June 2025, clams will be collected by a local SUBA diver. In July 2025, clams will be collected by SCUBA diving from a small local boat or by collection at low tide. Up to 25 clams will be collected at each station during each sampling period for a maximum total of 200 clams. After sampling, clams will be measured, photographed and either frozen or preserved in 10% formaldehyde. The frozen clams will be brought back to DFO Winnipeg in coolers. In the DFO laboratory or on site at the new research centre, tissue samples will be collected for fatty acid analysis to examine food web structure. The remaining tissue will be dissected to determine the gonadal development stage during a microscopic analysis. At the same locations where clams are collected, sea ice, water and sediment samples will be collected to investigate microalgal biomass, diversity and fatty acid content. Sea ice cores will be sampled using a Kovacs Ice Corer. The bottom 3 cm of the ice will be melted and filtered for analyses of ice algae taxonomy, chlorophyll a, particulate organic carbon/nitrogen, and fatty acids. Additionally, one ice core will be sampled to assess physical ice conditions including temperature and conductivity down the full length of the ice. Water profiles of conductivity, temperature, depth, and light will be measured at each station using a Maestro CTD sense to characterize physical water column properties. Water samples at the surface, middle and near bottom will be collected using a pump (surface only) and niskin bottles. Water will be processed for nutrients, salinity, phytoplankton taxonomy, chlorophyll a, particulate organic carbon/nitrogen, fatty acids and highly branched isoprenoids (HBI's). Surface sediment samples may be collected by the diver or by using a shovel at low tide at each location. Surface sediments will be analyzed for particulate organic carbon/nitrogen, fatty acids and How, when, and with whom research results will be shared.Following data collection, we plan to provide an update to the Nattivak HTA on the sampling activities in person and by written communication. We will also continue to contribute to the DFO led Coastal Environmental Baseline Program yearly newsletters. Once analyses is completed, we will provide a written summary of findings to the Nattivak HTA and will work closely with the Coastal Environmental Baseline Program on a coordinated effort to ensure the data is publicly available.

Uiviititut: This project does not take place in the city of Iqaluit. If French translation is still required, please contact me directly. Thank you.

Avatiliriniqmut Ayurhautingit:

We do not anticipate environmental impacts from our sampling work. Clams will be handpicking by a local Inuit diver and possibly digging during low tide. This means there will be no bycatch and that total number of clams sampled will not exceed our sample design of 25 per site per season. No scientific equipment will be left in the water. The use of local snowmobiles and a local boat will require gasoline to operate. Snowmobiles will be fueled at the local COOP gas station, mitigating any potential spills from jerry cans. The local boat will require fueling which will take place in the harbor only when seas are calm. We will also provide spill absorbent clothes to the local boat operator to wipe up any potential fuel drops onto the boat.

Qanurittuq Ittunik Avatinga: Avatingalluanga

This project is funded by DFO's coastal environmental baseline program which aims to collect marine baseline data in anticipation of the proposed deep seaport in Qikiqtarjuaq. The marine environment where we will be working consists of coastal marine waters influenced by Baffin Bay. We will be sampling primarily from the land fast ice sea ice that forms between Baffin Island and Broughton Island. This landfast first year ice is considered stable with ice breakup usually occurring in early July.

Qanurittuq Ittunik Avatinga: Inuuhimayunut Avatinga

Soft shell clams (Mya truncata) are abundant within the channel between Broughton Island, where the community of Qikiqtarjuaq is, and Baffin Island. This is owing to the sandy and mixed substrate seafloor and currents that flow through the north-south oriented channel which provides food to these filter feeding clams. This region is also known as a productive area for both sea ice algae in spring and phytoplankton in open water season, which likely also contributes to the abundant softshell clam population in the area.

Qanurittuq Ittunik Avatinga: Inungit-maniliurutingit Avatinga

Soft-shell clams are an important subsistance food for many people in Qikiqtarjuaq with the potential for a future local fishery. This project could provide future support by describing the reproductive cycle of the clams. Additionally, this project will employ a local Inuit SCUBA diver, and two Inuit field supports to collect clams in the spring and summer from four locations which may cost as much as $10, 000 for their services. Sampling will take place with local Inuit guides. We will employ two Inuit guides per trip ($180/guide/day) out on the ice for a maximum of eight sampling days. We will rent snowmobiles and komatiks directly from a local outfitter for a rate of $250/day/snowmobile. During the spring field program, our project will provide $2,880 in salaries and $4000 for snowmobile rental. In July, we will rent a local Inuit owned and operated boat for sampling at a rate of $2,350.00 for four sampling trips ($9400). In total, anticipate that this project will contribute $22, 280 in local revenue and employment within the community of Qikiqtarjuaq in 2025.

Miscellaneous Project Information

Naunaiyainiq ukuninnga Ayurhautingit unalu Piumayaat Ikikliyuumiutinahuarutit

Impacts from this project will be minimal. Clams will be handpicked by a local Inuit scuba diver and possibly hand dug at low tide. This greatly reduces any disturbance to the seafloor and the potential of collecting unwanted bycatch. No scientific instrument (e.g., temperature and salinity profiler) or sampling equipment (e.g., water sampler, ice sampler) will be left unattended in the water. All equipment will return with researchers.

Tamatkiumayunik Ihuikgutivaktunik

This project will contribute to baseline data collection as part of the Coastal Environmental Baseline program led by DFO. Baseline data will be used to assess any potential future environmental changes as a result of the proposed deep seaport and/or climate change. Additionally, this project will provide employment to local Inuit diver and outfitter. In total, we anticipate that this project will contribute $22, 280 in local revenue and employment within the community of Qikiqtarjuaq in 2025.
