NIRB Application for Screening #126248
Hook Lake Project

Application Type: New

Project Type: Mineral Exploration

Application Date: Thursday, December 18, 2025

Period of operation: from 2026-07-24 to 2026-10-23

Project Proponent:
Eric Sondergaard
6106 Resources Ltd
3139 Leduc Crescent S.W.
Calgary Alberta T3E 5X1
Canada
Phone Number:: 4038094982, Fax Number::

DETAILS

Non-technical project proposal description

English: 6106 Resources Limited (the Company) is an exploration company based out of Calgary Alberta and is a subsidiary of Manhattan Corporation. The Hook Lake Project is located within the Rankin-Ennadai greenstone belt. The Rankin – Ennadai is the second largest greenstone belt in Canada, however the area has seen only minimal exploration and detailed geological mapping. At Hook Lake, mineralization within the project consists primarily of gold, with various other metals including silver, copper and zinc. The Company holds mineral claims on both Crown Land and Inuit Owned Land (IOL). In July 2025 a Land Use License was granted by the Kivalliq Inuit Association (KVL125B05), for exploration activities on Inuit Owned Land (IOL) parcels AR-16, AR-23, WC-10, and RI-23. No Land Use Permit was required for exploration on Crown Land as there was no water use or camp. Exploration activities including surface rock sampling, geological observations and location of historic core samples took place at the project site approximately 140 km northwest of Arviat. These activities were helicopter supported, based out of Arviat. No camp was used at that time. The Company is now proposing to continue exploration activities including drilling, electro-magnetic (EM)surveys, ground and air geophysics, prospecting and sampling and to build a small, temporary exploration camp (20-person) to support the activities. It is proposed that the camp could be built in the Spring, and that exploration activities carry on until the Fall of 2026 and remain closed during the Winter months. The camp could be accessed via air in the summer and perhaps via trail from Arviat during winter depending on permissions. Mobilization of equipment and supplies to the proposed camp location, could take place in the Spring with the help of local contractors experienced in Arctic conditions. A specific site for the camp has not been chosen at this time, but rather a general location, which may be on Crown or Inuit Owned Land (see map). Once more information is obtained from local knowledge holders, a specific site will be chosen and regulators advised. In order to support these activities, the Company is applying for a Type 111 Land Use License from the Kivalliq Inuit Association (KIA), a Type B Land Use Permit for exploration activities on Crown Land, and a Type B Water License from the Nunavut Water Board for water use, and waste disposal. Mineral exploration activities have been undertaken in this area for many years, with gold first discovered in 1948, and work completed on all mineral claims by previous proponents. 6106 Resources Ltd. strongly respects the wildlife, the environment and the advice of local knowledge holders regarding timing and migration of wildlife and will abide by the terms and conditions of all licenses and permits. At the advice of the Arviat CLARC, Kivalliq Inuit Association's Mobile Protection Measures would be adhered to. Previous engagement by Eric Sondergaard took place via the KIA who held two CLARC meetings on April 15 2024 and June 12th 2024. After thorough review, the Arviat CLARC members are in support of the work plan, as it brings potential employment opportunities to the community members of Arviat. The Arviat HTO has been informed about the potential project actives and location, as well as the recommendations by the CLARC committee. Additional information regarding wildlife sensitivities has been sought, and 6106 Resources is optimistic for an open, constructive dialogue. In person meetings have been offered by the company as the permitting process advances. Its worth noting that Mineral exploration activities have been undertaken in this area for many years, including on portions of mineral claims and agreements by previous proponents. These overlapping exploration activities have been subject to a number of previous Nunavut Impact Review Board (NIRB) screenings, NPC review, and further screening may not be required (NIRB File 21EN009, NPC File No 149463, 16EN035).6106 Resources has a high regard for the environment and for the people on who's land they are exploring and intends to work hard to gain their respect. In order to do that, they will work within the terms and conditions of all their licenses and permits and seek the advice and experience of local knowledge holders. 6106 Resources Ltd. plans to conduct meaningful community consultation as well as meetings with the Hunter's and Trappers Organization (HTO) and the KIA Community Lands and Resources Committee (CLARC) in the Winter of 2026. Employment and business opportunities are somewhat modest at this early stage of mineral exploration but every effort will be made to prioritize benefits to Arviat

French: 6106 Resources Limited (la société) est une société d'exploration basée à Calgary (Alberta) et une filiale de Manhattan Corporation. Le projet Hook Lake est situé dans la ceinture de roches vertes Rankin-Ennadai. La ceinture Rankin-Ennadai est la deuxième plus grande ceinture de roches vertes au Canada, mais la région n'a fait l'objet que d'une exploration et d'une cartographie géologique détaillée minimales. À Hook Lake, le projet se caractérise par une

minéralisation principalement aurifère, ainsi que par la présence de divers autres, dont l'argent, le cuivre et le zinc. La société détient des titres miniers sur des terres de la Couronne et des terres appartenant aux Inuits (TAI). En juillet 2025, un permis d'utilisation des terres a été accordé par l'Association inuite du Kivalliq (KVL125B05) pour des activités d'exploration sur les parcelles AR-16, AR-23, WC-10 et RI-23 de terres appartenant aux Inuits (TAI). Aucun permis d'utilisation des terres n'a été requis pour l'exploration sur les terres de la Couronne, car il n'y a pas eu d'utilisation d'eau ou de campement. Les activités d'exploration, notamment l'échantillonnage de roches en surface, les observations géologiques et la localisation d'échantillons de carottes historiques, ont eu lieu sur le site du projet, à environ 140 km au nord-ouest d'Arviat. Ces activités ont été menées à bien à l'aide d'hélicoptères basés à Arviat. Aucun campement n'a été utilisé à ce moment-là. La Société propose désormais de poursuivre les activités d'exploration, y compris le forage, les levés électromagnétiques (EM), la géophysique terrestre et aérienne, la prospection et l'échantillonnage, et de construire un petit campement d'exploration temporaire (20 personnes) pour soutenir ces activités.. Il est proposé que le campement soit construit au printemps et que les activités d'exploration se poursuivent jusqu'à l'automne 2026, le campement restant fermé pendant les mois d'hiver. Le campement serait accessible par avion en été et peut-être par un sentier depuis Arviat en hiver, sous réserve des autorisations nécessaires. La mobilisation du matériel et des fournitures vers l'emplacement proposé pour le campement pourrait avoir lieu au printemps avec l'aide d'entrepreneurs locaux ayant l'expérience des conditions arctiques. À l'heure actuelle, aucun site précis n'a été choisi pour le campement, mais plutôt un emplacement général, qui pourrait se trouver sur des terres appartenant à la Couronne ou aux Inuits (voir la carte). Une fois que davantage d'informations auront été obtenues auprès des détenteurs de connaissances locales, un site précis sera choisi et les autorités réglementaires en seront informées. Afin de soutenir ces activités, la société demande un permis d'utilisation des terres de type 111 à l'Association inuite du Kivalliq (AIK), un permis d'utilisation des terres de type B pour les activités d'exploration sur des terres de la Couronne et un permis d'utilisation des eaux de type B auprès de l'Office des eaux du Nunavut pour l'utilisation de l'eau et l'élimination des déchets. Des activités d'exploration minière sont menées dans cette région depuis de nombreuses années. De l'or y a été découvert pour la première fois en 1948, et les travaux ont été menés à bien sur toutes les concessions minières par les promoteurs précédents. 6106 Resources Ltd. respecte profondément la faune, l'environnement et les conseils des détenteurs de connaissances locales concernant le temps de passage et la migration de la faune, et se conformera aux conditions de toutes les licences et de tous les permis. Sur les conseils du CTRC d'Arviat, les mesures de protection mobile de l'Association inuite du Kivalliq seront respectées. La mobilisation antérieure d'Eric Sondergaard s'est faite par l'intermédiaire de l'AIK, qui a tenu deux réunions du CTRC le 15 avril 2024 et le 12 juin 2024. Après un examen approfondi, les membres du CTRC d'Arviat appuient le plan de travail, car il offre des possibilités d'emploi aux membres de la communauté d'Arviat. L'OCT d'Arviat a été informé des activités potentielles du projet et de son emplacement, ainsi que des recommandations du comité CTRC. Des informations supplémentaires concernant la vulnérabilité de la faune ont été demandées, et 6106 Resources est optimiste quant à la possibilité d'un dialogue ouvert et constructif. La société a proposé des réunions en personne à mesure que le processus d'obtention des permis avance. Il convient de noter que des activités d'exploration minière ont été entreprises dans cette région depuis de nombreuses années, y compris sur des portions de claims miniers et d'accords conclus par des promoteurs antérieurs. Ces activités d'exploration qui se chevauchent ont déjà fait l'objet d'un certain nombre d'évaluations par la Commission du Nunavut chargée de l'examen des répercussions (CNER) et de la Commission d'aménagement du Nunavut (CAN), et il n'est peut-être pas nécessaire de procéder à d'autres évaluations (dossier CNER 21EN009, dossiers CAN n° 149463, 16EN035).6106 Resources accorde une grande importance à l'environnement et aux personnes sur les terres desquelles elle mène ses activités d'exploration, et entend tout mettre en œuvre pour gagner leur respect. À cette fin, elle respectera les conditions générales de toutes ses licences et de tous ses permis et sollicitera les conseils et l'expérience des détenteurs de connaissances locales. 6106 Resources Ltd. prévoit de mener des consultations publiques significatives ainsi que des réunions avec l'Organisation des chasseurs et trappeurs (OCT) et le Comité des terres et des ressources communautaires (CTRC) de l'AIK à l'automne 2025. Les possibilités d'emploi et d'affaires sont plutôt modestes à ce stade précoce de l'exploration minière, mais tous les efforts seront faits pour donner la priorité aux retombées pour Arviat.

Project transportation types

Transportation Type	Proposed Use	Length of Use
Air	delivery of goods and fuel, transport crew from small temporary camp to exploration areas/drill sites	

Project accomodation types

Temporary Camp

Material Use

Equipment to be used (including drills, pumps, aircraft, vehicles, etc)

Equipment Type	Quantity	Size - Dimensions	Proposed Use
helicopter	1	Bell 407 or similar	Drill moves, crew transport
twin otter	1	16 m long	Resupply and equipment
snowmachines	1-8	200 kg	Transport to/from drills, geophysics, camp support
snowmachines	1-8	200 kg	Transport to/from drills, geophysics, camp support
ATV and trailer	1-4	500 kg	Transport equipment and supplies
inflatable boat	1-2	zodiac or equivalent	Lake bathymetry
diesel generator	1-2	20 kw diesel generator or similar	camp power
water pumps	1-2	10 kg	generator; Drill Rig/camp support
freezer	1	standard	domestic purposes
stove	1	30	domestic purposes
fridge	1	standard	domestic purposes
generator	2	20 kw	Camp/ water pumps
water pump	2	Honda WT20XK4C or equivalent	camp water
incinerator	1	dual chamber	incinerate combustible waste
Pacto toilets	4	standard	human waste disposal
clothes washer	1	standard	domestic clothes washing
clothes dryer	1	standard	domestic clothes drying
Toyo stove	13	L731/732 or equivalent	tent heat
RC Hornet or equivalent reverse circulation drill	1-3	4,400 (all components)	rock chip sampling
Boyles 25A/37 or equivalent diamond drill	1-2	8,600 including rods and casings	rock core sampling
solids removal equipment	1-2	3000 kg each	remove solids from drill water
Frost Fighter Heaters	1-4	150 kg	heat drill shacks
generators	1-4	5 kw Gasoline generator or equivalent	power for water pumps for drilling

Detail Fuel and Hazardous Material Use

Detail fuel material use:	Fuel Type	Number of containers	Container Capacity	Total Amount	Units	Proposed Use
Diesel	fuel	200	205	41000	Liters	Generator/heating/drill support
Aviation	fuel	200	205	41000	Liters	helicopter / twin otter refueling

fuel						
Propane	fuel	30	100	3000	Lbs	cooking
Gasoline	fuel	10	205	2050	Liters	camp support/Snowmachine/ATV/generator
Other	fuel	50	20	1000	Liters	oil for generator; Drill Rig/camp support
Other	fuel	50	20	1000	Liters	drill lubricants
Other	fuel	50	20	1000	Liters	drill mud additives
diesel	hazardous	200	205	41000	Liters	Generator/heating/drill support
Aviation Fuel	hazardous	200	205	41000	Liters	helicopter and twin otter fuel
gasoline	hazardous	10	205	2050	Liters	camp support/Snowmachine/ATV/generator
propane	hazardous	30	100	3000	Lbs	cooking
oil	hazardous	50	20	1000	Liters	oil for generator; Drill Rig/camp support

Water Consumption

Daily amount (m3)	Proposed water retrieval methods	Proposed water retrieval location
299	pump from nearby water source	nearby water source

Waste

Waste Management

Project Activity	Type of Waste	Projected Amount Generated	Method of Disposal	Additional treatment procedures
Mineral Exploration	Combustible wastes	unknown but expected to be minimal	waste from lunches and paper waste, incinerated in a dual chambered incinerator	ash collected and stored in sealed 45 gallon drums and transported to an approved facility
Camp	Combustible wastes	unknown but expected to be minimal	incinerate in dual chambered incinertator	ash collected and stored in sealed 45 gallon drums and transported to an approved facility
Camp	Greywater	unknown but expected to be minimal	depression on the tundra located at least 31 metres above the ordinary high water mark of any water body	buried at the end of the season
Fuel and chemical storage	Hazardous waste	unknown but expected to be minimal	stored separately in secondary containment.	collected in sealed 45 gallon drums and transported to an approved facility for disposal
Drilling	Hazardous waste	unknown but expected to be minimal	stored separately in secondary containment.	collected and stored in a sealed 45 gallon drum and transported to an approved facility for disposal
Camp	Sewage (human waste)	unknown but expected to be minimal	pacto toilets	incinerate in dual chambered incinerator. ash collected and stored in sealed 45 gallon drums and transported to an approved facility for disposal.

Environmental Impacts:

The imposed mitigation measures described in the "Additional Information" are set out to ensure the exploration area is in the same or better condition than prior to exploration activities. Further to the mitigation, the company will abide by the terms set out in any licenses and permits granted to allow exploration activities. Further mitigation measures will be implemented as required to address any arising issues.

Additional Information

SECTION A1: Project Info

SECTION A2: Allweather Road

SECTION A3: Winter Road

SECTION B1: Project Info

6106 Resources plans to conduct an initial drill program in 2026 to verify historic results and find areas of high gold and silver potential. If promising the project would continue seasonally in spring/summer and/or winter winter over following years.

SECTION B2: Exploration Activity

Satellite remote sensing may be used to acquire high resolution satellite imagery or hyperspectral data. This would be undertaken completely remotely by a 3rd party expert contractor. The area of investigation would be limited to 6106 mineral claims/exploration agreements. Samples of soil and other sediments may be completed. This would involve the collection of a small bag of soil from a 10x10cm hole, dug by hand. The tundra vegetation on top would be carefully removed and replaced after sampling. On land drilling will be completed using primarily a diamond drilling rig, such as the Zinex A5 or similar, to recover drill core for geological logging, cutting and sampling for shipment to a laboratory for preparation, digestion and analysis. Reverse Circulation drilling may also be used, for example a Super Hornet heli portable rig. Reverse Circulation drilling produces “chip” samples which will be collected at the drill site through a cyclone and“riffle-splitter” or similar into composite samples, usually spanning a 5ft interval. On ice drilling (typically diamond drilling) Drilling as described above will primarily be completed on land, however if required todemonstrate continuity within the mineralisation drilling may be conducted in a similar manner on ice. On site sample processing will be limited to the geological logging of rock type, alteration and mineralisation, along with basic measurements using a portable X-Ray Fluorescence device (pXRF) and magnetic susceptibility tool (KT-10). After logging, the drillcore will be cut over specific intervals using a diamond saw, with half of the drillcore being assigned a sample ID and bagged for shipping to a laboratory off-site. Off site sample processing. All samples prepared on site from drilling and rock chip sampling activities will be shipped off-site to a certified laboratory, for example ALS Laboratories, Yellowknife. The samples will then undergo crushing, pulverising, splitting, digestion in acids and then analysis. This will quantify the concentration of elements of interest within the samples.

SECTION B3: Geosciences

Geophysical surveys may be conducted to gain information about the subsurface without intrusive methods. Magnetic data can be acquired either by ground surveys, which involves walking a number of straight lines across the target area carrying a magnetometer device, or airborne methods. Airborne methods involve a similar line based approach, but with a fixed wing or helicopter to cover the distance. Electromagnetic (EM) surveys may also be used, which can be completed by ground or airborne means. Ground EM surveys involve laying cables in a set configuration and the creation of a current through the cables via battery power or generators. Measurements are then taken on foot within the loop of cable and the response recorded, indicating the conductivity/resistivity of the subsurface. Aerial photography will be conducted, this will likely be completed via helicopter and is an alternative/supplement to satellite data collection. Ground penetrating radar may be used to confirm lake depths. Geological maps already exist for the project area. Detailed geological mapping may be completed over certain target areas in conjunction with rock chip sampling. All drillcore or chips generated from diamond drilling or reverse circulation drilling will be logged for geology. This will form a 3D geological model of the target areas. Geophysical surveys completed via fixed wing or helicopter may require periods of lower altitude flying. No aerial surveys will be undertaken during times of increased wildlife sensitivity when herds of caribou are observed in the project area.

SECTION B4: Drilling

The number of drillholes is highly dependent on the results of the first phase of results. However, a maiden drilling program may be expected to consist of up to 25 drillholes to approximately 80 in a year where promising results have been found. Primarily diamond drills will be used, however reverse circulation drilling may be used where suitable. Reverse circulation drills do not require water usage. Drillhole depth will vary depending on the target area, however initial diamond drillholes may average 250-300m depth with deeper holes extending to 400-500m depth to test extensions of mineralisation. Reverse circulation drillholes will likely average 200m. No additives to be used with reverse circulation drilling, diamond drilling may use calcium chloride as an additive to water to assist when drilling through permafrost. Drill cuttings from diamond drilling will be directed to a nearby natural depression/sump with the drilling water being re-circulated downhole. Drilling equipment will be moved via helicopter. During winter, with sufficient snow coverage drilling equipment may be dragged on skids.

Description of Existing Environment: Physical Environment

The Hook Lake Project is located within the Kivalliq Region of Nunavut. The main study area, covered by mineral claims and exploration agreements is located 135km northwest of Arviat, the nearest settlement. The area has a history of mineral exploration. The Project, consisting of mineral claims on Crown Lands and Surface Inuit Owned Lands and Exploration Agreements on Inuit Owned Lands Surface and Subsurface. There is no known overlap with protected areas. The wider project area encapsulates a route to Arviat, to maintain the possibility of a winter trail between the exploration areas and the settlement. Geology is dominated by volcano-sedimentary rocks of Archean age, They trend east-west to northeast-sothwest within the Rankin-Ennadai Greenstone Belt. They have been deformed and metamorphosed to greenschist facies with local higher metamorphic grade in the vicinity of large igneous plutons. Gold mineralisation was discovered in the 1960s at Turqueil Lake with work programs extending into the 1980s, consisting of geological mapping, rock sampling, soil sampling, airborne and ground geophysics and substantial drilling programs. Copper, zinc and silver mineralisation is also present and has been subject to extensive previous mineral exploration. The project area has several eskers, which are trending NW/SE. There are also areas mapped as "Sand" and "Tundra Polygon" which are typical landforms for the tundra landscape. Topography is generally flat with small rocky outcrops which in places are rounded due to glaciation. Seasonal temperature variation across the project area is pronounced. Average winter daytime temperatures in the surrounding Kivalliq–Ennadai region reach approximately –24 °C, with nighttime lows near –32 °C, while summer daytime highs average around +15 °C. Broader Nunavut climate data indicate winter averages ranging between –26 °C and –12 °C, and summer averages from +2 °C to +9 °C. Strong prevailing westerly winds are typical. Lakes in the region generally remain frozen until early to mid-May, followed by a cool, rainy season beginning in late August. Air quality in the area is expected to generally be good due to the remote location and minimal industrial activity, although wildfires activity can impact air quality periodically. Noise levels are also expected to be low due to the remote location. The area is one of contiguous permafrost, which can extend to a depth of 160 m or more and reach temperatures as low as -15°C. Although waterbodies in the region are generally pristine in nature, natural geology and environmental inputs and flow processes can cause water quality to vary by waterbody and season. The project area encapsulates several large waterbodies of note, including Heninga Lake, Carr Lake, Turquetil Lake, Kaminak Lake and Maguse Lake towards Arviat.

Description of Existing Environment: Biological Environment

The Project area is in a predominantly treeless Southern Arctic Tundra. Vegetation is comprised of grasses, lichens, low shrubs, mosses, and various arctic flowering plants. A limited abundance of spruce, willows, alders, and ground birch can be found in sheltered niches along lake edges or watercourses. The Aquatic life in the freshwater environments include species such as Arctic char, lake trout, northern pike and Arctic grayling. Project lies within the range of the Qamanirjuaq barren ground caribou herd. The calving period of June 9 to June 22 is a particularly sensitive time for the caribou herd, which currently is predominantly located NW of Whale Cove, which is further NE than the project area. Other mammals include moose, muskox, grizzly bears, wolverines, arctic ground squirrels, wolves and arctic fox. Polar bears are present along the coast of Hudson Bay but rarely move far enough in land to be present within the project area. Within the Kivalliq region there are favourable habitats for birds such as waterfowl-geese and ducks, shorebirds such as sandpipers, and raptors like falcons and hawks. Notable examples include the Ross's goose, snow goose, peregrine falcon and rough-legged hawk. Many of these species utilise the Kuugaarjuk Migratory Bird Sanctuary which is south of Arviat, outside of the Project area. There are no known official species at risk within the project area. There are also no know National Wildlife Areas, Migratory Bird Sanctuaries or Other Conserved Areas in the Project area as per the National Protected and Conserved

Areas Network of Canada.

Description of Existing Environment: Socio-economic Environment

The project is located 135km northwest of Arviat, in the Kivalliq Region of Nunavut. The project covers Crown land and Inuit owned surface and subsurface land. Exploration Agreements with the NTI are in place on Inuit owned land with subsurface rights. 6106 Resources are not aware of any archaeological or culturally significant sites in the Project Area but will avoid any sites that are identified over time. The bedrock geology is dominated by Archean aged rocks, which would be host to only microfossils, and so the palaeontological aspect is limited. The project will significantly add to the subsurface geological knowledge of the Rankin-Ennadai Greenstone Belt, an important source of gold for Nunavut. The project, due to its remote location is not expected to effect human health, local or regional traffic patterns. 6106 Resource acknowledges the traditional land use in the Kivalliq Region, with importance of harvesting practices. The project location is 135km inland from Arviat, and is not expected to interrupt harvesting practices. 6106 Resources is committed to working with the Arviat HTO, Kivalliq Inuit Association and the Hamlet of Arviat, over the life of the project. 6106 Resources will also preferentially use Arviat, Kivalliq, and Nunavut-based businesses, maximizing local employment, providing on-the-job and other training opportunities, and supporting community initiatives as requested and feasible.

Miscellaneous Project Information

Identification of Impacts and Proposed Mitigation Measures

Physical Impacts1. Designated environmental areas:No designated environmental areas occur within the Project footprint. A winter trail may be used by low-pressure vehicles (e.g., tracked or skid-mounted) to connect Arviat with the Hook Lake Camp (final location TBD).2. Ground stability:Effects on ground stability will be minimized by avoiding areas highly sensitive to exploration, directing runoff into sumps to prevent land scouring, and protecting permafrost (as described below). Given these measures, along with the small scale and limited extent of activities, no significant effects on ground stability are expected.3. Permafrost:Permafrost could be affected by heated structures, drilling operations, and unfilled sumps. To reduce potential impacts, the camp will be placed on dry, stable terrain, avoiding wetlands. Heated tents and drill shacks will be elevated on cribbing to promote air flow and limit ground warming. Any excavated sumps or depressions near drill collars will be backfilled at closure to prevent water ponding and subsequent permafrost degradation. With these measures and the modest scale of the program, no significant permafrost impacts are anticipated.4. Hydrology / limnology:Water may be drawn from lakes, streams, ponds, or rivers near the camp and drill sites. Although 6106 Resources is requesting a cumulative withdrawal limit of up to 299 m^3/day (Type B Water Licence threshold), typical use is expected to remain below 100 m^3/day and occur on fewer than 100 days per year on average.Drill water use will be minimized by recycling and reusing drill water, settling and removing cuttings, and/or using a freshwater tank to eliminate repeated intake from lakes. Together, these practices can reduce water demand by up to 90%.Under-ice withdrawals will not exceed 10% of available water volume, determined in accordance with DFO's Protocol for Winter Water Withdrawal or the Mackenzie Valley Land and Water Boards' Technical Reference Document.No significant impacts on hydrology or limnology are expected.5. Water quality:Water quality could be influenced by spills, sump releases, or drilling effluent. Biodegradable drilling additives will be used where possible, and drilling on ice will avoid the use of salt and operate with a closed fluid loop. Sumps will be located at least 31 m from the ordinary high water mark and managed according to best practices. All chemicals will be stored at least 31 m from water and handled in accordance with the Spill Contingency Plan. With these mitigation measures in place, no significant impacts on water quality are anticipated.6. Climate conditions:Given the limited scale and nature of the proposed work, no impacts on climate are anticipated.7. Eskers and other unique/fragile landscapes:Eskers are present within the exploration area. Impacts will be minimized by avoiding sensitive terrain, managing runoff through sumps to reduce land scouring, and protecting permafrost as described earlier. No significant effects on these landforms are predicted.8. Surface and bedrock geology:The nature and scale of the Project are not expected to cause significant effects on surface or bedrock geology. Geological knowledge of the area will be enhanced through exploration.9. Sediment and soil quality:Sediment and soil may be affected by spills, sump discharges, or drilling activities. Biodegradable drilling additives will be used where possible, drilling on ice will avoid salt and use closed circuits, and sumps will be placed at least 31 m from the ordinary high-water mark and managed in accordance with best practices. . Chemicals will be stored at least 31 m from water, and spill response measures outlined in the Spill Contingency Plan will be followed. No significant impacts on sediment or soil quality are expected.10. Air quality:Air quality may be influenced by emissions

from fuel combustion or waste incineration. 6106 Resources will reduce emissions by limiting helicopter use and equipment run-times, performing preventative maintenance, minimizing open burning, burning only appropriate waste streams (e.g., untreated wood, paper, cardboard), and using a dual-chamber, forced-air incinerator designed for the waste types generated. Given these measures and the scale of the Project, no significant impacts on air quality are expected.11. Noise levels:Noise from camp operations, drilling, and helicopter use may disturb wildlife. Noise will be localized, intermittent, and short-term. Work will cease if wildlife approaches any site. Additional measures include reducing idling and unnecessary flights, maintaining equipment to reduce noise, and following the Wildlife Management and Monitoring Plan. No significant noise impacts are anticipated.Biological Impacts1. Vegetation:Vegetation effects from the Project footprint will be reduced by:i. Minimizing overall footprint through consolidation of structures and materialsii. Locating the camp on dry, durable ground to reduce erosion and ground disturbanceiii. Using previously disturbed areas (e.g., airstrips) where feasibleiv. Elevating heated tents and drills on cribbing to reduce vegetation disturbance and permafrost thawv. Avoiding off-road vehicle use when rutting or gouging could occurvi. Reducing winter trail and winter road size by minimizing corridor length and width and using existing trails where possiblevii. Using natural depressions or sumps for liquid waste, and backfilling any dug sumps after use to support revegetationviii. Minimizing salt use during drilling by substituting calcium chloride for sodium chloride, which is more harmful to plantsix. Preventing non-native species introduction by cleaning equipment prior to mobilizationx. V-notching winter stream crossings before melt to prevent unnatural pondingxi. Locating sumps, fuel storage, and infrastructure more than 31 m from waterbodiesxii. Avoiding areas with identified sensitive featuresxiii. Progressively closing drill sites and fly camps to limit cumulative disturbancexiv. Stabilizing areas susceptible to erosion or sediment loss at closureWith these measures and the small scale of the Project, no significant vegetation impacts are predicted.2. Wildlife, birds, wildlife habitat, and migration patterns:Project activities may affect wildlife habitat or cause disturbance. In addition to the habitat-protection measures above, 6106 Resources will implement mitigation to:A) reduce disturbance to wildlife, dens, and nestsB) minimize wildlife attractionC) limit helicopter-related disturbanceD) reduce direct wildlife impactsReducing disturbance to wildlife, dens, and nests:i.Closely monitor activities during Qamanirjuaq caribou calving and post-calving (June 9–22 and June 23–July 3) and halt work if caribou approach. Abide by the KIA's Mobile Mitigation Measuresii. Avoid habitat disturbance during the bird nesting season when possibleiii. Maintain a 300 m buffer from bird concentrations (e.g., colonies, molting sites)iv. If active nests are located, stop disruptive work until nesting is complete and establish species-appropriate buffersv. Avoid drilling near active carnivore densvi. Skirt camp tents to deter wildlife denningB) Reducing wildlife attraction:i. Enforce a strict no-feeding-wildlife policyii. Store food waste and attractants securely and in ways that reduce odoursiii. Require crews to return all food scraps to camp for proper managementiv. Dispose of attractant wastes promptly via backhaul or approved onsite incinerationv. Do not establish a landfill, as it may attract wildlifevi. Screen kitchen greywater to remove food particles and treat sumps with lime or lye as neededvii. Train personnel in waste-management procedures designed to reduce attractionviii. Install a bear fence if necessaryix. Conduct routine inspections to verify that attractants are controlled and food waste is managed appropriatelyC) Minimizing helicopter disturbance:i. Halt exploration, including flights, if Qamanirjuaq caribou approach during calving/post-calvingii. Avoid unnecessary low-level flights or landings near wildlifeiii. Fly above 610 m altitude whenever possible and not below 300 m except for operational needsiv. Adjust flight paths to avoid wildlife when low flying is requiredv. Maintain a 1,100 m vertical buffer over bird concentrationsvi. Maintain a 1.5 km lateral buffer from bird colonies and molting areasvii. Detour flights around wildlifeviii. Conduct wildlife scans before landing and avoid landing near animalsD) Minimizing direct wildlife impacts:i. Enforce a strict no-hunting policyii. Permit fishing only with proper licencesiii. Provide bear-awareness and deterrence trainingiv. Equip crews with deterrence gear (e.g., air horns, bear bangers, spray) and train themv. Use bear fences where requiredvi. Use wildlife monitors when appropriatevii. Avoid deliberate approach to wildlifeviii. Train all workers on wildlife-related policies and waste-management practicesix. Check active work areas for signs of wildlife access or new nestingWith these measures and the limited scale of activities, no significant impacts to wildlife, birds, habitat, or migration patterns are expected.3. Aquatic species, habitat, and migration/spawning:All water intake lines will be screened to avoid entraining or impinging fish, and DFO-recommended mitigation measures will be followed or guidance sought as needed. No in-water construction is planned. With these actions, no significant impacts on aquatic species or habitat are anticipated.4. Wildlife protected areas:The exploration program does not overlap any wildlife protected areas.Socioeconomic Impacts1. Archaeological and cultural historic sites:Ground disturbance from the camp and drill sites could affect archaeological or cultural sites. If areas of potential significance are identified, an archaeologist will be engaged to assess possible camp and drill locations. Archaeological assessments will continue as required over the life of the Project. Although no known archaeological or cultural sites occur within the mineral claims, any discovered sites will be avoided. With these measures and the small scale of the Project, no significant impacts are anticipated. If any areas are discovered, exploration activities will cease in that area and cordoned off. The site will then be reported to the Government of Nunavut, chief archaeologist. 2. Employment:The Project is expected to provide positive employment

benefits. 6106 Resources will prioritize contracting with Arviat, Kivalliq, and Nunavut businesses, maximize local hiring, and offer on-the-job and other training opportunities. With established mining operations already present in the region, an experienced workforce is available. Overall, the Project is expected to contribute positively to regional employment.3. Community wellness:Community wellness is expected to benefit from increased employment, local business participation, and 6106 Resources' support for community initiatives. Overall impacts on community wellness are anticipated to be positive.4. Human health:Due to the remote location, small scale, and the mitigation measures described throughout the application, no impacts on human health are expected.

Cumulative Effects

Exploration activities by 6106 resources are all anticipated to be of limited scale and impact and will be mitigated to avoid significant residual impacts. However, residual impacts must be considered in combination with those of other projects undertaken in the past, present, or future, to confirm that even individually-limited impacts are unlikely to result in significant cumulative impacts. Exploration activities have been considerable in the Rankin-Ennadai Greenstone Belt (geological province) which now hosts world class gold deposits and mining operations, such as the Meliadine and Meadowbank Complex mines of Agnico Eagle. This gold mining activity is a considerable, long term positive socio-economic impact with a very limited surface footprint. 6106 Resources exploration activity would add to this. 6106 mineral claims and exploration agreements are in areas of previous exploration activity. Cumulative effects of exploration are expected to have mitigatable negative impacts. In this area, the highest potential for negative cumulative effect, should there be one, is on the Qamanirjuaq barren-ground caribou herd, who utilise the area as habitat. Care is to be taken during the calving and post calving periods, which sees the herd to the NE of the Project area. To mitigate during this time of the year winter access is considered, making use of significant snow cover to drag resupplies and equipment to the camp, reducing the number of helicopter and/or float plane flights required during more sensitive periods of the year. With significant mitigation measures in place, no significant cumulative negative impacts are anticipated.
