# DÉTAILS

## Description non technique de la proposition de projet

Anglais: The Government of Nunavut (Transportation and Infrastructure) is proposing to improve the sealift area in the Hamlet of Sanikiluaq, located on the Belcher Islands in Hudson Bay. The Project is in the Qikiqtani (Qikiqtaaluk, Baffin) Region within the municipal boundaries of the Hamlet of Sanikiluaq, at approximately 56°32.4' N and 79°15.0' W. The current sealift area is functional but limited by space and a relatively short tidal operating window. The area consists primarily of a gravel pad and with an uneven surface. There is one main access point though other access points are also used, particularly by ATVs. The intertidal zone is an extension of the gravel surface leading to a sloped beach composed of soft sands and gravels. The shallow subtidal zone is characterized by smaller cobbles and rocks. The area appears to be relatively unproductive due presumably to freezing and ice scour conditions that occur annually as well as the regular access by vehicles (largely trucks and ATVs). Tides at Sanikiluaq are diurnal (2x per day) and relatively subdued with a typical range of approximately +/-1 m between low and high tide. Improvements to the current sealift area would involve: 1. Expanding the sealift laydown area by placing gravel and fill, particularly to even out the surface; surface grading; and placing riprap armouring along the outside perimeter of the marine interface to protect against erosion and ice scour. 2: Widening the barge landing area to accommodate two barges simultaneously through gravel and fill placement and grading; and resloping the ramp/barge landing area to allow access during low tides. 3. Upgrading the entry/exit points and adding signage. The Project will not require new supporting infrastructure such as roads, borrow sources, or quarries, as current access to the sealift area is sufficient and deposits developed by the Hamlet of Sanikiluaq will be utilized for granular material and riprap. Aggregate sites are available both to the east and west of Sanikiluaq and are relatively close to the Project site (e.g., within 5 km). The estimated size of the current sealift area is approximately 0.4 ha (4,200 m<sup>2</sup>). The expanded size, including the laydown area, widened barge landing ramp, and protective riprap armouring would be approximately 1.1 ha (10,925 m<sup>2</sup>), adding approximately 0.7 ha or 6,725 m<sup>2</sup> of area to the current space used for the sealift and laydown. Construction would be seasonal, occurring ideally during the summer of 2026 but may require additional time in the summer of 2027 to complete. The estimated number of days on site is 90 (45 days each year), staffed by 7 people operating equipment. Anticipated environmental effects resulting from the Project are expected to be limited given that much of the area is already disturbed by the current sealift operation as well as by general public access. The Project footprint has been optimized to occur within areas of existing terrestrial disturbance. Potential effects to the marine environment will be limited by carrying out activities "in the dry" where possible, during falling or low tide conditions and would avoid placing materials in the shallow subtidal zone during the restricted timing window for fall spawning fish in Nunavut (August 15 to June 30). Additional mitigation measures include: • Verifying all construction-related equipment arrives on site in a clean condition. • Use of spill kits sized appropriately for the equipment involved, including spill kits within the construction area. • Vehicle maintenance, including washing, refueling, and servicing, to be carried out in areas well away from water. • Storage of fuel and other chemicals or lubricants will be well away from water. • Erosion and sediment control practices (e.g., silt fencing, stopping in periods of heavy rain etc.) will be practiced during Project implementation. With the implementation of the mitigation measures proposed, it is anticipated that potential effects (harm) to the terrestrial environment and fish and fish habitat related to the construction and future operation of the Sanikiluaq sealift improvement project can be avoided and/or limited.

Français: Le Gouvernement du Nunavut (Transports et Infrastructures) propose d'améliorer la zone de transport maritime dans le Hameau de Sanikiluaq, situé sur les Îles Belcher dans la Baie d'Hudson. Le Projet se trouve dans la Région de Qikiqtani (Qikiqtaaluk, Baffin), à l'intérieur des limites municipales du Hameau de Sanikiluaq, à environ 56°32,4' N et 79°15,0' O. La zone actuelle de transport maritime est fonctionnelle, mais limitée par l'espace et une fenêtre d'exploitation par marée relativement courte. La zone est principalement composée d'une aire de gravier et d'une surface inégale. Il y a un point d'accès principal, bien que d'autres points d'accès soient aussi utilisés, particulièrement pour les véhicules tout-terrain (VTT). La zone intertidale est une extension de la surface de gravier menant à une plage en pente composée de sables fins et de gravier. La zone subtidale peu profonde se caractérise par de plus petits galets et rochers. La zone semble relativement improductive, vraisemblablement en raison des conditions de gel et de frottement de la glace qui surviennent chaque année,

# Déchets

## Gestion des déchets

Activités du projet	Type des déchets	Quantité prévue	Méthode d'élimination	Procédures de traitement supplémentaires
Information is not available				

### Répercussions environnementales :

Some disturbance to the terrestrial environment is expected and has been offset by limiting the size of the overall project footprint. Disturbance to intertidal and shallow subtidal aquatic habitat is anticipated through the placement of gravel and riprap armouring. The habitat is generally of lower productivity due to annual ice formation and scour during the winter as well as regular access by people and vehicles, including barge traffic. Efforts will be made to limit effects to the intertidal and shallow subtidal zones by avoiding material placement during the restricted timing window for fall spawning fish (Aug 15-Jun 30). Erosion and sediment control practices will also be in effect during construction. Motorized equipment will be equipped with spill kits as will the construction area generally. Equipment will be in good repair prior to arriving at site and will be kept in good repair for the duration of the Project. Refueling and repairs will be carried out at established facilities within Sanikiluaq (i.e., away from water).

### **Description de l'environnement existant : Environnement physique**

The current sealift area is characterized by a gravel pad and with an undulating surface.

### **Description de l'environnement existant : Environnement biologique**

The upland/terrestrial area is largely unvegetated with some areas composed of dwarf woody vegetation and grasses. The intertidal zone is composed of a sloped beach composed of soft sand and gravel. The shallow subtidal zone supports smaller cobbles and rocks.

### **Description de l'environnement existant : Environnement socio-économique**

The Hamlet of Sanikiluaq is serviced by the current sealift and laydown area. Improvements to the sealift as proposed would result in positive benefits to the community through employment opportunities during construction and improved operability and service of the sealift area over the longer-term.

## **Miscellaneous Project Information**

### **Identification des répercussions et mesures d'atténuation proposées**

Some disturbance to the terrestrial environment is expected and has been offset by limiting the size of the overall project footprint. Disturbance to intertidal and shallow subtidal aquatic habitat is anticipated through the placement of gravel and riprap armouring. The habitat is generally of lower productivity due to annual ice formation and scour during the winter as well as regular access by people and vehicles, including barge traffic. Efforts will be made to limit effects to the intertidal and shallow subtidal zones by avoiding material placement during the restricted timing window for fall spawning fish (Aug 15-Jun 30). Erosion and sediment control practices will also be in effect during construction. Motorized equipment will be equipped with spill kits as will the construction area generally. Equipment will be in good repair prior to arriving at site and will be kept in good repair for the duration of the Project. Refueling and repairs will be carried out at established facilities within Sanikiluaq (i.e., away from water).

### **Répercussions cumulatives**

No cumulative effects are anticipated.
