ᖃᓪᓗᓈᑎᑐᑦ: Evaluation of the Geothermal Potential of Iqaluit Ysaline Bacon1, Xavier Leveillee Dallaire1, and Pr. Jasmin Raymond11 Institut National de la Recherche Scientifique (INRS), Québec, Canada The project evaluates the geothermal potential of Iqaluit, Nunavut, to support decarbonization and energy autonomy for northern communities. Context and justification: northern settlements are heavily dependent on imported diesel for heat and power, resulting in high costs, logistical vulnerability and negative environmental impacts. Territorial knowledge gaps (particularly limited data on geothermal gradients, subsurface thermal properties and fracture-network characteristics) have hindered reliable design and risk assessment for both shallow ground-source heat pumps (GSHPs) and deeper enhanced geothermal systems (EGS). There is also strategic interest from the Department of National Defence in decarbonizing northern operations; consequently, site selection prioritizes locations that could serve both civilian energy needs (residential and commercial heating, potential electricity) and military resilience. Two technological pathways are targeted: GSHPs for space heating and EGS - using fractured deep reservoirs - aimed at heat extraction and electricity generation.Short-term objectives (2025–2026) concentrate on targeted field acquisition. This summer campaign within a 10-km radius of Iqaluit will collect 20–30 representative surface rock samples across crystalline basement, sedimentary sequences and surficial/fractured units to obtain thermal conductivity, volumetric heat capacity and density. Systematic scanline fracture surveys on outcrops will document fracture orientation, spacing, aperture and connectivity to parameterize permeability and potential fluid pathways relevant to EGS screening. Prior to and during fieldwork the team will engage local and Indigenous organizations to co-design culturally appropriate protocols, communicate objectives, and incorporate community priorities into site selection and dissemination plans. All field activities will be non-invasive (surface sampling and observational mapping) and avoid collection of sensitive Indigenous knowledge.Long-term objectives (2026–2030) aim to expand regional understanding and produce decision-ready analyses for potential pilot deployments. Laboratory measurements will feed into numerical models to estimate local geothermal gradients, predict thermal responses for GSHP systems accounting for permafrost and latent-heat effects, and simulate reservoir behaviour for candidate EGS targets including uncertainty quantification. Techno-economic assessments will determine levelized cost of heat and electricity, lifecycle performance, logistical constraints for Arctic deployment, risk allocation for exploratory drilling, and staged implementation scenarios (e.g., GSHP demonstrators preceding exploratory wells). Outputs will explicitly compare geothermal options with diesel baselines to inform community and defence stakeholders.Data management and dissemination emphasize transparency, accessibility and local relevance. Validated datasets (thermal property measurements, fracture characterizations, analytical calculations, modelling outputs and non-sensitive imagery) Chaire de recherche du Canada sur l'analyse des systèmes géoénergétiques durables will be archived at INRS and, following validation and peer review, deposited in Borealis and the Northern Geothermal Database to support reuse across northern Canada. Anticipated outputs include doctoral theses, peer-reviewed articles, conference presentations and plain-language materials for community briefings. Knowledge mobilization will prioritize iterative feedback sessions, visual materials and locally appropriate communication channels.The project commits to culturally respectful engagement, environmental safeguards for sampling and site visits, and long-term availability as a technical resource for communities and decision-makers. By closing critical data gaps and producing transparent, locally relevant assessments, the project aims to enable informed pathways for geothermal pilot projects that advance low-carbon, resilient energy systems for Iqaluit and other northern communities.

ᐅᐃᕖᑎᑐᑦ: Évaluation du potentiel géothermique d'IqaluitYsaline Bacon[1], Xavier Leveillee Dallaire[1] et Pr. Jasmin Raymond[1][1] Institut national de la recherche scientifique (INRS), Québec, CanadaLe projet évalue le potentiel géothermique d'Iqaluit, au Nunavut, afin de soutenir la décarbonation et l'autonomie énergétique des communautés nordiques.Contexte et justificationLes collectivités du Nord dépendent fortement du diesel importé pour le chauffage et la production d'électricité, ce qui entraîne des coûts élevés, une vulnérabilité logistique et des impacts environnementaux négatifs. Les lacunes dans les connaissances du territoire — notamment le manque de données sur les gradients géothermiques, les propriétés thermiques du sous-sol et les caractéristiques des réseaux de fractures — ont freiné la conception fiable et l'évaluation des risques, tant pour les systèmes géothermiques peu profonds à pompe à chaleur (GSHP) que pour les systèmes géothermiques stimulés en profondeur (EGS).Le

ministère de la Défense nationale manifeste également un intérêt stratégique pour la décarbonation des opérations nordiques. Ainsi, la sélection des sites vise des emplacements pouvant répondre à la fois aux besoins énergétiques civils (chauffage résidentiel et commercial, production potentielle d'électricité) et à la résilience militaire. Deux filières technologiques sont ciblées :GSHP : pompes à chaleur géothermiques pour le chauffage des bâtiments ;EGS : systèmes géothermiques stimulés exploitant des réservoirs fracturés profonds pour extraire de la chaleur et produire de l'électricité.Objectifs à court terme (2025–2026)Les objectifs immédiats portent sur une campagne de terrain ciblée. Cet été, dans un rayon de 10 km autour d'Iqaluit, 20 à 30 échantillons représentatifs de roches de surface seront prélevés dans le socle cristallin, les séquences sédimentaires et les unités superficielles ou fracturées. Ces échantillons serviront à mesurer :la conductivité thermique ;la capacité calorifique volumique ;la densité.Des relevés systématiques des fractures sur affleurements permettront aussi de documenter :l'orientation des fractures ;leur espacement ;leur ouverture ;leur connectivité.Ces données serviront à estimer la perméabilité et les voies potentielles de circulation des fluides, essentielles pour évaluer les possibilités EGS.Avant et pendant les travaux, l'équipe collaborera avec des organisations locales et autochtones afin de coélaborer des protocoles culturellement appropriés, expliquer les objectifs du projet et intégrer les priorités communautaires dans le choix des sites et la diffusion des résultats. Toutes les activités de terrain seront non invasives (échantillonnage de surface et cartographie d'observation) et excluront la collecte de savoirs autochtones sensibles.Objectifs à long terme (2026–2030)Les objectifs futurs visent à approfondir la compréhension régionale et à produire des analyses directement utiles à la prise de décision pour d'éventuels projets pilotes.Les mesures de laboratoire alimenteront des modèles numériques pour :estimer les gradients géothermiques locaux ;prédire la réponse thermique des systèmes GSHP en tenant compte du pergélisol et des effets de chaleur latente ;simuler le comportement de réservoirs candidats pour l'EGS, avec quantification des incertitudes.Des analyses technico-économiques permettront d'évaluer :le coût actualisé de la chaleur et de l'électricité ;la performance sur le cycle de vie ;les contraintes logistiques propres à l'Arctique ;les risques liés au forage exploratoire ;des scénarios de déploiement progressif (ex. démonstrateurs GSHP avant forage profond).Les options géothermiques seront comparées explicitement aux solutions actuelles au diesel afin d'éclairer les décideurs communautaires et militaires.Gestion des données et diffusionLe projet met l'accent sur la transparence, l'accessibilité et la pertinence locale. Les ensembles de données validés (propriétés thermiques, caractérisation des fractures, calculs analytiques, résultats de modélisation et imagerie non sensible) seront archivés à l'INRS puis, après validation et évaluation scientifique, déposés dans Borealis et dans la Northern Geothermal Database afin de favoriser leur réutilisation à l'échelle du Nord canadien.Les retombées prévues comprennent :des thèses doctorales ;des articles scientifiques évalués par les pairs ;des présentations en conférence ;du matériel vulgarisé pour les communautés locales.Le transfert des connaissances reposera sur des rencontres de rétroaction régulières, des supports visuels et des moyens de communication adaptés au contexte local.Engagement du projetLe projet s'engage à maintenir un dialogue respectueux sur le plan culturel, à appliquer des mesures de protection environnementale lors des visites et échantillonnages, et à demeurer une ressource technique durable pour les communautés et les décideurs.En comblant des lacunes critiques en données et en produisant des évaluations transparentes et ancrées localement, ce projet cherche à ouvrir des voies réalistes vers des projets pilotes géothermiques favorisant des systèmes énergétiques sobres en carbone et résilients à Iqaluit ainsi que dans d'autres communautés nordiques.

Small rock samples will be collected, resulting in very low environmental impact. No drilling, excavation, or use of heavy machinery is planned. Potential impacts are minor and localized, including slight disturbance to surface materials and vegetation at sampling sites. Mitigation measures include conducting activities near existing roads and previously disturbed areas, avoiding environmentally and culturally sensitive sites (e.g., archaeological areas and cemeteries), limiting vegetation disturbance by targeting exposed bedrock outcrops only, and minimizing the number and size of samples collected. A strict “leave no trace” approach will be followed, including the removal of all waste. While immediate impacts are negligible, the study may contribute, in the longer term, to positive environmental and socioeconomic outcomes by improving knowledge of geothermal potential and supporting more informed energy decisions in Nunavut. This may also indirectly support employment opportunities, infrastructure planning, self-governance, and energy sovereignty.

ᒫᓐᓇ ᐊᑭᑎᐅᑉ ᖃᓄᐃᑦᑐᓪᓚᕆᐅᓂᖓ: ᓄᓇᐅᑉ ᖃᓄᐃᑦᑑᓂᖓ

Iqaluit is located on the southeastern coast of Baffin Island, within a sub-Arctic to Arctic climate characterized by long, cold winters and short, cool summers. The region is underlain by continuous to discontinuous permafrost, which strongly influences ground thermal regimes and subsurface hydrology. Surface conditions are dominated by tundra vegetation, thin soils, and widespread exposed crystalline bedrock of the Canadian Shield.Topography is generally low-relief but locally controlled by glacially scoured outcrops and frost-related processes. Seasonal freeze–thaw cycles affect near-surface stability, while snow cover and ice conditions vary significantly throughout the year. The area is also influenced by coastal processes from Frobisher Bay, including sea ice formation and tidal effects.Freshwater resources are limited to lakes and small streams, many of which are frozen for most of the year. Infrastructure development is constrained by permafrost, requiring adapted construction practices. Overall, the physical environment presents significant logistical and technical challenges for subsurface investigations and energy development.

ᒫᓐᓇ ᐊᑭᑎᐅᑉ ᖃᓄᐃᑦᑐᓪᓚᕆᐅᓂᖓ: ᐆᒪᔪᖅᑕᖃᕐᓂᖓ

The biological environment around Iqaluit is characteristic of Arctic tundra ecosystems, with low biodiversity but high ecological sensitivity. Vegetation is dominated by mosses, lichens, grasses, and low-growing shrubs adapted to cold temperatures, shallow active layers, and nutrient-poor soils. Plant growth is limited to a short growing season, making recovery from disturbance slow.Wildlife includes terrestrial species such as caribou (notably the Baffin Island population), Arctic fox, and polar bear, although encounters near the city are occasional. The area also supports small mammals and a variety of migratory bird species during the summer breeding season.Marine and coastal ecosystems linked to Frobisher Bay are biologically productive and support species such as seals and fish, which are important for local subsistence. These ecosystems are closely tied to seasonal sea ice dynamics.Overall, Arctic ecosystems are particularly vulnerable to disturbance due to slow regeneration rates, strong seasonal constraints, and tight coupling between climate, permafrost, and biological activity.

ᒫᓐᓇ ᐊᑭᑎᐅᑉ ᖃᓄᐃᑦᑐᓪᓚᕆᐅᓂᖓ: ᐃᓄᓕᕆᓂᕐᒨᖓᔪᑦ-ᐱᕙᓪᓕᐊᔪᓕᕆᓂᕐᒨᖓᔪᑦ

Iqaluit is the capital of Nunavut and serves as the primary administrative, economic, and transportation hub of the region. The population is predominantly Inuit, and local livelihoods are shaped by a mix of wage-based employment (government, services) and traditional land-based activities such as hunting, fishing, and harvesting.The community faces a high cost of living, driven by its geographic isolation and reliance on air and seasonal sea transport. Energy supply is almost entirely dependent on diesel generation, resulting in high energy costs, logistical vulnerability, and environmental concerns. As a result, there is strong interest in alternative and locally available energy sources.Infrastructure development is constrained by permafrost, limited road networks, and the absence of connections to southern electrical grids. Cultural

and archaeological considerations are central to any project in the region. Inuit knowledge plays an important role in land use planning, and certain areas may hold cultural significance or contain archaeological remains, requiring avoidance or careful management.

Miscellaneous Project Information

na

ᓇᓗᓇᐃᖅᑕᐅᓂᖏᑦ ᐊᒃᑐᖅᑕᐅᓯᒪᔪᑦ ᖃᓄᐃᑦᑑᓂᖏᑦ ᐸᓚᐅᒥᒡᔪᓯᖅᑕᐅᓂᐊᕐᓂᖏᓪᓗ

The project involves surface fracture observations and small rock sample collection, resulting in very low environmental disturbance.Activities will be conducted near existing roads and previously disturbed areas, while avoiding environmentally and culturally sensitive sites (e.g., archaeological areas and cemeteries). No heavy equipment will be used, and sampling will be kept to a minimum.A strict “leave no trace” approach will be followed, including the removal of all waste. Research objectives and results will be shared with local communities.Overall, the project is expected to have negligible environmental and socioeconomic impacts.

Cumulative Effects

Given the small scale and short duration of the proposed activities, the project is not expected to contribute significantly to cumulative adverse environmental effects.Activities are limited to surface observations and small sample collection near existing roads, with no infrastructure development or long-term disturbance.However, the project may contribute positively at a cumulative level by improving knowledge of local geothermal potential, supporting more informed energy decision-making in Nunavut, where communities currently rely heavily on diesel.
