DÉTAILS

Description non technique de la proposition de projet

Anglais:	Collection and growth monitoring of sclerochronological organisms to understand hydro-ecological changes in Baffin Bay Primary Applicant: Natasha Leclerc, Université Laval Background and Justification Phytoplankton (microalgae) provide essential ecosystem services, including carbon sequestration and supporting marine food webs. Their abundance and composition vary across seasons and years in response to nutrient availability, sea-ice cover, light, and temperature. Understanding how phytoplankton dynamics have changed over the past centuries can improve our knowledge of carbon cycling and food availability in Arctic ecosystems. Establishing baseline information for Qikiqtarjuaq is particularly important given ongoing environmental change, the planned industrial port development, and the importance of phytoplankton to traditional foods such as clams and fish. Phytoplankton influence ocean chemistry, making long-lived organisms that record chemical conditions during growth valuable archives of past environmental change. Clams and the coralline alga <i>Clathromorphum compactum</i> are examples of such organisms. They can live for decades to centuries and produce annual growth layers similar to tree rings. Analysis of these layers can provide insights into long-term changes in ocean chemistry and phytoplankton dynamics since industrialization. Objectives The project aims to collect clams and coralline algae for geochemical analyses to quantify temporal changes in phytoplankton dynamics in coastal regions of Baffin Bay near Qikiqtarjuaq. This will be achieved through: Collection of clams and thick coralline algal crusts around Qikiqtarjuaq. Deployment of a one-year coralline algae growth-monitoring platform. In collaboration with other research teams operating near Qikiqtarjuaq, we will minimize environmental impacts and reduce demands on community members participating in research activities. Methods and Timeline Fieldwork will begin in August 2026 and continue through October 2029, laying the foundation for future historical reconstructions of phytoplankton dynamics. Activities will be supported by Université Laval's Research Station and involve a team of 4–6 visiting scientists and, ideally, 4–6 community members. Work will involve near-monthly SCUBA dives and boat-based sampling. 1. Coralline algae survey and specimen collection (August–September 2026) In conjunction with a kelp forest survey led by Camille Lavoie (NRI approved), we will conduct a coralline algae survey using drop-down cameras and SCUBA. Thick coralline algal crusts will be sampled opportunistically using a hammer and chisel, with a maximum of 100 samples collected per site. Clams will also be collected opportunistically throughout the project, and shells will be retained for geochemical analyses at Université Laval. 2. Coralline algae growth-monitoring platform Following site selection, 100–120 small coralline algal crusts will be collected and marked with a non-toxic dye (e.g., alizarin) to establish the start of the growth experiment. Specimens will be attached using underwater cement to PVC plates secured to the seafloor with steel rods or rock bolts, depending on substrate type. Sensors measuring temperature, salinity, light, pH, and photosynthetically active radiation (PAR) will be attached to the platform and exchanged during near-monthly dives to reduce fouling-related measurement errors. During these visits, 8–10 coralline algal crusts will also be collected by SCUBA. At the end of the experiment, the platform will be removed. Collected specimens will be returned to Université Laval for analysis. Water samples (1 L) will be collected for carbonate and nutrient chemistry analyses, and sediment samples will be collected for biogeochemical characterization. Community Involvement A key component of this project is the incorporation of Inuit Knowledge and the involvement of Qikiqtarjuaq community members, many of whom have expressed interest in understanding historical ecosystem change. We will provide opportunities for training in diving and laboratory techniques and employ local boat operators and field technicians throughout the project. Local divers have already played an important role in identifying potential collection sites through their observations and experience underwater. The project will contribute to community-based environmental monitoring and support discussions regarding ongoing changes affecting coastal ecosystems in the region. Knowledge Sharing Plan We will provide annual reports to the Hamlet and HTA, present project updates during each community visit, and deliver outreach activities at the local school. Final results will be shared with the HTA through a formal presentation, published in open-access journals, and presented at scientific conferences with Inuit partners whenever possible (e.g., ArcticNet and the European Geosciences Union).

Activités du projet	Type des déchets	Quantité prévue	Méthode d'élimination	Procédures de traitement supplémentaires
Researching	Déchets non combustibles	5 lbs	Some packaging waste from equipment shipment will be sent to the Qikiqtarjuaq landfill. No other waste is expected.	N/A

Répercussions environnementales :

The proposed project is expected to have minimal environmental impacts. Potential negative but mitigable impacts are limited to temporary increases in noise and human presence associated with vessel and snowmobile travel, which may cause short-term disturbance to wildlife, including marine mammals, seabirds, and aquatic species. These effects are expected to be localized, infrequent, and of short duration. Mitigation measures will include minimizing time spent at sampling locations, avoiding close approaches to wildlife, maintaining appropriate setback distances from marine mammals and birds, conducting activities in accordance with local wildlife guidelines, and suspending or relocating activities if sensitive species are observed nearby. No habitat alteration, resource depletion, pollution, waste disposal, or long-term infrastructure development is proposed. The project is expected to have positive socioeconomic impacts through local employment, collaboration with community members and organizations, support for environmental monitoring, and contributions to knowledge of marine ecosystems that are important for food security and community well-being. Communication with the community will be maintained throughout the research period through local radio, Facebook, and regular contact with the Qikiqtarjuaq Research Centre to ensure concerns can be identified and addressed promptly. Species listed under the Species at Risk Act (SARA), including polar bear, bowhead whale, narwhal, and certain seabird species, may occur within the broader region. The project is not expected to adversely affect listed species, their critical habitat, or residences due to its non-destructive nature and implementation of wildlife avoidance measures. No significant cumulative, transboundary, or non-mitigable effects are anticipated.

Description de l'environnement existant : Environnement physique

The proposed study area is located in the marine environment surrounding Qikiqtarjuaq, Nunavut, and does not overlap with Auyuittuq National Park, protected wildlife areas, or other formally designated protected areas. The area is culturally important to the community and is regularly used for travel, harvesting, fishing, and hunting activities. Marine and sea-ice covered habitats within the region support a variety of species, including marine mammals, Arctic char, clams, seaweed, marine fish, seabirds, polar bears, and Arctic foxes. The surrounding landscape and seascape are also valued for their scenic beauty and cultural significance. Water quality in the region is generally considered high; however, localized influences may occur near the community due to wastewater discharge, fuel storage and handling, vessel traffic, shoreline disturbance, runoff, and historical waste sites. No significant impacts on these environmental or cultural values are anticipated, as project activities are limited to non-destructive marine scientific research and environmental monitoring. The project will not restrict access to these areas or involve activities expected to adversely affect wildlife habitat, water quality, or harvesting activities.

Description de l'environnement existant : Environnement biologique

The marine environment surrounding Qikiqtarjuaq is of significant socioeconomic and cultural importance to the local Inuit community. Marine resources support subsistence harvesting, food security, cultural practices, recreation, tourism, and local economic activities. The area is regularly used for travel by boat and snowmobile and is valued for its scenic beauty and connection to Inuit culture and traditional knowledge. Marine vegetation is dominated by macroalgae, including kelp and other benthic algal communities that provide habitat and food for a variety of marine organisms. The region supports diverse wildlife populations, including ringed, harp, and bearded seals, narwhal, bowhead whales, polar bears, and Arctic foxes. Wildlife movements and habitat use are strongly influenced by seasonal sea-ice conditions. The area also provides important habitat for numerous seabird species, with migratory birds using coastal and marine habitats for feeding, nesting, and staging during the summer months. The project area does not overlap with any designated seabird protection areas. Aquatic species include Arctic char, Greenland halibut, Arctic cod, capelin, sculpins, clams, and other marine invertebrates. Nearshore benthic habitats support shellfish, seaweed communities, and other organisms important to local food webs. Several species occurring in the region may be listed under the federal Species at Risk Act (SARA) or territorial conservation frameworks, including polar bear, bowhead whale, narwhal, and certain seabird species. The proposed research activities are limited to non-destructive marine scientific research and environmental monitoring and are not expected to adversely affect wildlife, habitats, migration routes, or harvesting activities.

Description de l'environnement existant : Environnement socio-économique

The project area is located in the marine environment adjacent to the hamlet of Qikiqtarjuaq, approximately 1-110 km from the community depending on sampling or surveying location. The area is regularly used by

Inuit for travel, harvesting, fishing, hunting, and other land- and sea-based cultural activities. Marine resources contribute significantly to local food security, cultural continuity, recreation, tourism, and the local economy. While no archaeological, palaeontological, or culturally significant sites are known to occur within the marine project footprint, the surrounding region contains numerous Inuit cultural landscapes, traditional travel routes, harvesting areas, and archaeological sites of cultural and historical importance. Any previously unidentified cultural resources encountered during project activities would be reported to the appropriate authorities. The area experiences seasonal vessel, snowmobile, and small-aircraft traffic associated with community activities, harvesting, tourism, research, and resupply operations. Local resource use includes subsistence harvesting of marine mammals, fish, seabirds, shellfish, and other country foods, as well as tourism, guiding, and wildlife viewing activities. Human health and well-being in the region are closely linked to access to country foods, environmental quality, cultural practices, and opportunities for safe travel on the land and sea ice. The proposed research activities are limited in scale, non-destructive, and are not expected to adversely affect community well-being, resource use, cultural values, navigation, or harvesting activities. Other valued socioeconomic components identified through community engagement and regional studies include food security, cultural continuity, knowledge sharing, environmental stewardship, and access to marine resources.

Miscellaneous Project Information

Identification des répercussions et mesures d'atténuation proposées

The proposed project is expected to have minimal environmental and socioeconomic impacts. Project activities are limited to small-scale, non-destructive marine scientific research and environmental monitoring. No construction, blasting, fuel caching, waste disposal, or long-term infrastructure installation is proposed. Potential negative impacts are expected to be minor, temporary, and mitigable. These may include short-term disturbance from vessel or snowmobile activity, noise, or the presence of researchers in marine areas used by wildlife and community members. Mitigation measures will include minimizing time on site, avoiding close approaches to wildlife, maintaining clean field practices, preventing the release of waste or contaminants, and coordinating activities with local partners to avoid interference with harvesting, travel, or culturally important activities. Communication with the community will be maintained throughout the research period through local radio, Facebook, and regular contact with the Qikiqtarjuaq Research Centre. These communication channels will provide opportunities for community members to raise concerns or identify potential impacts, allowing project activities to be clarified, modified, or relocated where appropriate. Potential socioeconomic impacts are expected to be neutral to positive. The project may contribute to local knowledge, environmental monitoring, research capacity, and understanding of marine ecosystems important to food security and community well-being. No adverse effects on human health are anticipated. The project will not restrict access to travel routes, hunting areas, fishing areas, or other marine resource-use areas. No transboundary effects are anticipated, as project activities are localized near Qikiqtarjuaq and do not involve emissions, discharges, habitat alteration, or activities likely to affect areas outside the local study area. Species listed under the federal Species at Risk Act (SARA), including polar bear, bowhead whale, narwhal, and certain seabird species, may occur regionally. The project is not expected to adversely affect listed species, their critical habitat, or residences. Researchers will avoid disturbance to wildlife, maintain appropriate distances from marine mammals, birds, and polar bears, and suspend or relocate activities if sensitive species are observed nearby. Overall, identified impacts are expected to be either positive or negative but mitigable. No negative non-mitigable impacts are anticipated. Monitoring will occur through field observations, documentation of any wildlife interactions or unusual environmental conditions, and ongoing communication with local partners and community members.

Répercussions cumulatives

The proposed project is not expected to contribute meaningfully to cumulative environmental effects. Activities are limited to small-scale, non-destructive marine scientific research and environmental monitoring and will not result in significant habitat alteration, resource depletion, pollution, or long-term infrastructure development. While the project will occur within a region that experiences ongoing community activities, harvesting, tourism, marine transportation, and research, its contribution to cumulative effects is expected to be negligible due to its limited spatial extent, short duration, and low-intensity nature. The project is not expected to interact with past, present, or reasonably foreseeable future activities in a manner that would result in significant cumulative environmental or socioeconomic effects.
