APPENDIX A

Wildlife Observations

Wildlife Observations						
Date	**Time**	**Location**	**Wildlife Species**	**Quantity**	**Observer Name #1**	**Observer Name #2**
JANUARY 2020						
January 9, 2020	12:52 PM	Haul Road	Arctic Fox	1	Joe Putumiraqtuq	Derek Nateela
January 10, 2020	12:17 PM	Haul Road	Musk Ox	1	Joe Putumiraqtuq	Derek Nateela
January 15, 2020	2:07 PM	Haul Road	Arctic Hare	2	Joe Putumiraqtuq	Derek Nateela
January 16, 2020	1:42 PM	Haul Road	Caribou	5	Joe Putumiraqtuq	Derek Nateela
January 17, 2020	2:37 PM	AWAR	Musk Ox	100	Derek Nateela	Joe Putumiraqtuq
January 29, 2020	3:33 PM	Haul Road	Caribou	5	Joe Putumiraqtuq	Simon
FEBRUARY 2020						
February 5, 2020	7:04 PM	Haul Road	Caribou	5	Joe Putumiraqtuq	Simon
February 7, 2020	2:58 PM	AWAR	Arctic Hare	1	Joe Putumiraqtuq	Laurence Archambault
February 7, 2020	2:58 PM	AWAR	Ptarmigan	1	Joe Putumiraqtuq	Laurence Archambault
February 17, 2020	4:17 PM	Amaruq	Caribou	1	Derek Nateela	Isabelle Couture
February 19, 2020	12:20 PM	Haul Road	Caribou	5	Joe Putumiraqtuq	
February 19, 2020	12:20 PM	Haul Road	Musk Ox	30	Joe Putumiraqtuq	
February 25, 2020	5:54 PM	Haul Road	Caribou	2	Joe Putumiraqtuq	
February 25, 2020	5:54 PM	Haul Road	Caribou	13	Joe Putumiraqtuq	
February 25, 2020	5:54 PM	Haul Road	Musk Ox	2	Joe Putumiraqtuq	
February 26, 2020	1:49 PM	Haul Road	Caribou	2	Joe Putumiraqtuq	
February 26, 2020	1:49 PM	Haul Road	Caribou	1	Joe Putumiraqtuq	
February 27, 2020	12:48 PM	Haul Road	Arctic Fox	1	Joe Putumiraqtuq	
MARCH 2020						
March 4, 2020	3:31 PM	AWAR	Caribou	88	Joe Putumiraqtuq	
March 4, 2020	3:31 PM	AWAR	Caribou	39	Joe Putumiraqtuq	
March 5, 2020	2:51 PM	Amaruq	Caribou	2	Derek Nateela	Simon CB
March 5, 2020	2:51 PM	Amaruq	Musk Ox	2	Derek Nateela	Simon CB
March 10, 2020	6:07 PM	Haul Road	Arctic Fox	1	Joe Putumiraqtuq	
March 10, 2020	6:07 PM	Haul Road	Caribou	6	Joe Putumiraqtuq	
March 10, 2020	6:07 PM	Haul Road	Musk Ox	35	Joe Putumiraqtuq	
March 11, 2020	2:01 PM	AWAR	Caribou	30	Derek Nateela	
March 11, 2020	2:01 PM	AWAR	Caribou	200	Derek Nateela	
March 11, 2020	2:01 PM	AWAR	Caribou	30	Derek Nateela	
March 11, 2020	11:26 AM	Haul Road	Musk Ox	23	Joe Putumiraqtuq	
March 12, 2020	11:42 AM	Haul Road	Musk Ox	40	Joe Putumiraqtuq	
March 12, 2020	1:52 PM	AWAR	Caribou	26	Derek Nateela	
March 12, 2020	1:52 PM	AWAR	Caribou	4	Derek Nateela	
March 12, 2020	1:52 PM	AWAR	Caribou	75	Derek Nateela	
March 12, 2020	11:42 AM	Haul Road	Ptarmigan	13	Joe Putumiraqtuq	
March 13, 2020	12:18 PM	Haul Road	Musk Ox	46	Joe Putumiraqtuq	
March 13, 2020	12:18 PM	Haul Road	Caribou	46	Joe Putumiraqtuq	
March 13, 2020	12:18 PM	Haul Road	Caribou	196	Joe Putumiraqtuq	
March 13, 2020	1:03 PM	AWAR	Caribou	50	Derek Nateela	
March 13, 2020	1:03 PM	AWAR	Caribou	10	Derek Nateela	
March 13, 2020	1:03 PM	AWAR	Caribou	18	Derek Nateela	
March 13, 2020	1:03 PM	AWAR	Ptarmigan	10	Derek Nateela	
March 14, 2020	2:00 PM	AWAR	Caribou	53	Laurence Archambault	
March 14, 2020	2:00 PM	AWAR	Caribou	29	Laurence Archambault	
March 14, 2020	6:31 PM	Amaruq	Caribou	2	Derek Nateela	
March 17, 2020	10:36 PM	Amaruq	Caribou	22	Derek Nateela	
March 20, 2020	7:26 PM	Haul Road	Caribou	1	Isabelle Couture	
March 22, 2020	12:16 PM	Haul Road	Caribou	3	Isabelle Couture	
March 22, 2020	12:16 PM	Haul Road	Caribou	100	Isabelle Couture	
March 25, 2020	5:26 PM	AWAR	Caribou	6	Isabelle Couture	
March 25, 2020	5:26 PM	AWAR	Caribou	9	Isabelle Couture	
March 25, 2020	5:26 PM	AWAR	Caribou	15	Isabelle Couture	
March 25, 2020	5:26 PM	AWAR	Caribou	31	Isabelle Couture	
March 28, 2020	2:16 PM	AWAR	Caribou	26	Nicolas Saucier	
March 28, 2020	2:16 PM	AWAR	Caribou	8	Nicolas Saucier	
March 28, 2020	2:16 PM	AWAR	Caribou	12	Nicolas Saucier	
March 28, 2020	2:16 PM	AWAR	Caribou	80	Nicolas Saucier	
March 28, 2020	2:16 PM	AWAR	Ptarmigan	10	Nicolas Saucier	
March 28, 2020	2:16 PM	AWAR	Caribou	22	Nicolas Saucier	
March 28, 2020	7:33 PM	Haul Road	Caribou	1	Rowan Woodall	
March 28, 2020	7:33 PM	Haul Road	Caribou	16	Rowan Woodall	
March 29, 2020	2:44 PM	Haul Road	Caribou	75	Nicolas Saucier	
March 31, 2020	8:18 PM	Haul Road	Musk Ox	34	Laurence Archambault	Philip Roy
March 31, 2020	8:18 PM	Haul Road	Caribou	2	Laurence Archambault	Philip Roy
March 31, 2020	8:18 PM	Haul Road	Caribou	3	Laurence Archambault	Philip Roy
March 31, 2020	8:18 PM	Haul Road	Caribou	1	Laurence Archambault	Philip Roy
March 31, 2020	8:18 PM	Haul Road	Caribou	1	Laurence Archambault	Philip Roy
March 31, 2020	8:18 PM	Haul Road	Caribou	255	Laurence Archambault	Philip Roy
APRIL 2020						
April 1, 2020	10:16 AM	AWAR	American crow	2	Laurence Archambault	
April 1, 2020	11:00 AM	AWAR	American crow	1	Philip Roy	
April 1, 2020	1:16 PM	AWAR	Arctic Hare	3	Daphne Morin	
April 1, 2020	1:16 PM	AWAR	Caribou	6	Daphne Morin	

Wildlife Observations						
Date	**Time**	**Location**	**Wildlife Species**	**Quantity**	**Observer Name #1**	**Observer Name #2**
April 1, 2020	1:16 PM	AWAR	Caribou	20	Daphne Morin	Isabelle Couture
April 1, 2020	1:16 PM	AWAR	Caribou	20	Daphne Morin	
April 1, 2020	1:16 PM	AWAR	Caribou	24	Daphne Morin	
April 1, 2020	1:16 PM	AWAR	Caribou	250	Tom Thompson	Philip Roy
April 1, 2020	1:16 PM	AWAR	Caribou	60	Tom Thomson	
April 5, 2020	1:45 PM	Haul Road	Caribou	250	Daphne Morin	
April 5, 2020	1:45 PM	Haul Road	Ptarmigan	15	Laurence Archambault	
April 5, 2020	1:45 PM	Haul Road	Caribou	26	Louis Dubois	
April 5, 2020	1:45 PM	Haul Road	Caribou	27	Louis Dubois	
April 5, 2020	1:45 PM	Haul Road	Arctic Hare	10	Philip Roy	
April 5, 2020	1:45 PM	Haul Road	Caribou	2	Philip Roy	
April 5, 2020	1:45 PM	Haul Road	Caribou	6	Philip Roy	
April 5, 2020	1:45 PM	Haul Road	Caribou	8	Rowan Woodall	
April 5, 2020	1:45 PM	Haul Road	Caribou	21	Robin Allard	
April 5, 2020	1:45 PM	Haul Road	Caribou	25	Samuel Tapp	
April 5, 2020	1:45 PM	Haul Road	Caribou	4	Tom Thompson	Philip Roy
April 5, 2020	1:45 PM	Haul Road	Caribou	40	Tom Thompson	Philip Roy
April 5, 2020	1:45 PM	Haul Road	Caribou	50	Tom Thompson	Philip Roy
April 5, 2020	1:45 PM	Haul Road	Caribou	50	Tom Thomson	
April 6, 2020	12:32 PM	AWAR	American Crow	4	Philip Roy	
April 6, 2020	2:18 PM	AWAR	Caribou	11	Daphne Morin	Isabelle Couture
April 6, 2020	2:18 PM	AWAR	Caribou	11	Daphne Morin	
April 6, 2020	2:18 PM	AWAR	Grey Wolf	2	Daphne Morin	
April 6, 2020	2:18 PM	AWAR	Wolverine	1	Fanny Laporte	
April 6, 2020	2:18 PM	AWAR	Caribou	30	Fanny Laporte	
April 6, 2020	2:18 PM	AWAR	Caribou	62	Fanny Laporte	
April 6, 2020	2:18 PM	AWAR	Caribou	120	Nicolas Saucier

APPENDIX C

Wildlife Mortality Report (Caribou)

Wildlife Incident Report Form

Date:	2020-03-02	**Time:**	14:00
Individuals involved:	Rowan Woodall	Simon Charron Bigras	
	Nancy Duquet Harvey		
Species:	Caribou		
Number, gender, age:	1, male, juvenile		
Location (description):	AWAR Km 89 3m West of road		
Location (UTM):	64 58 18.266N / 96 13 17.059W		
Digital photo numbers:			

Describe the incident or accident that occurred. Was there a threat to wildlife or human safety? What was the situation that caused it?

A caribou corpse was spotted on the AWAR road at km 89 and reported to Nancy Duquet Harvey. She forwarded the information to Rowan Woodall. Him and Simon Charron-Bigras (Environmental Technicians) went to investigate, the caribou corpse was found at the reported location, 3 meters from the road, probably gutted by animals, frozen solid. While there was no traffic or wildlife incident reported to Agnico, the proximity to road and blood splatter suggests an interaction with traffic. Further investigation is ongoing.

Describe any use of wildlife deterrents: Describe any wildlife mortality:

There was some crows eating on the carcass but they fled when the technicians approached. No deterrents used.
One Caribou corpse found, probably gutted by animals.

Describe any communication with GN-DOE:

GN-DoE Russell Toolooktook was contacted by Nancy Duquet-Harvey on March 2, 2020. It was agreed that the carcass will be retrieved and delivered to the GN Conservation Office in Baker Lake. The Wildlife Mortality Report was sent on March 3, 2020.

What immediate measures were taken to reduce risk or harm?

No immediate risk, deterrents gear was brought in case of scavenger wildlife presence.

What measures are recommended to prevent future occurrences?

Report prepared by:	Simon CB	**Reviewed by:**	Nancy Duquet-Harvey

Picture 2: Carcass had been preyed upon by scavenging animals

Picture 3: Blood around read-end of carcass

APPENDIX D

Wildlife Mortality Reports

Wildlife Incident Report Form

Date:	2020-01-21	**Time:**	15:00
Individuals involved:	Tom Thomson – Env		
Species:	Wolverine		
Number, gender, age:	N/A		
Location (description):	North of Meadowbank Camp at the North Cell Tailings Sludge Dump		
Location (UTM):	14 W 0637278 7216072		
Digital photo numbers:	See below		

Describe the incident or accident that occurred. Was there a threat to wildlife or human safety? What was the situation that caused it?

Wolverine was trying to get access under the main camp (below kitchen grease trap). The wolverine was also observed numerous times near by the front doors of main camp, the smoke shack across from the front doors of the main camp, and the Incinerator. The wolverine had a tendency to run under the steps at the main camp when deterring efforts were used. Employees were getting worried of their safety working outdoors as the wolverine had become habituated to the front door/main camp area.

Describe any use of wildlife deterrents: Describe any wildlife mortality:

Between Jan 13 and Jan 20 – Environment responded to frequent calls for the Wolverine (min. 3 a day) at the main camp near the kitchen grease trap area. A number of methods were used to deter the animal away from site (Horn of pick up truck, Bangers, Screamers, and Rubber Bullets). The opportunity to deter more aggressively with snowmobile did not present itself after receiving approval on Jan 17.

On Jan 21 @ 14:00 during a patrol – the Wolverine was seen trying to dig it's way under the skirting around the main camp by the kitchen grease trap area. The wolverine was deterred with the horn of the truck. ENV returned to the scene approximately 20 minutes later and the wolverine again was trying to access the area. ENV was able to deter with bangers out to the tailings area. ENV Coordinator Tom Thomson had a clear shot at the animal and dispatched it at 15:00.

Describe any communication with GN-DOE:

Emails exchange between Meadowbank Environment Coordinators and GN Conservation Officers of Baker Lake on January 16, 2020. Approval of more aggressive deterring methods and wildlife destruction authorization received on January 17, 2020. Report of Wildlife destruction on January 21, 2020 @ 16:00 between Rob Arsenault (GN) and Tom Thomson (MBK ENV). The animal will be brought to the GN Conservation office on January 22, 2020.

What immediate measures were taken to reduce risk or harm?

Respond to sightings immediately
Hold tool box meetings with different departments
Ensure no food waste is present
Place additional gravel at the location where animal was trying to access

What measures are recommended to prevent future occurrences?

Continue to educate departments on Wildlife interactions, food waste and attractants.
Ensure additional gravel/material is compacted and placed at any gaps between skirting around the camp and ground.

Report prepared by:	Tom Thomson	Reviewed by:	Tom Thomson

APPENDIX E

Waterbird Mitigation Project – 2020 Progress Report

AGNICO EAGLE

MEADOWBANK COMPLEX

2020 Migratory Bird Protection Report

In Accordance with NIRB Project Certificate No.008

Prepared by:
Agnico Eagle Mines Limited – Meadowbank Complex

March, 2021

EXECUTIVE SUMMARY

Through collaboration with Trent University and ECCC, research studies were initiated in 2018 to determine the effectiveness of flood mitigation measures for migratory birds in the Whale Tail South area. The three objectives of this research study were to:

1. Determine the efficacy of various audio and visual deterrents (for preventing flood-zone nesting).
2. Estimate the number of nests and the species composition lost due to the flooding.
3. Examine the behavioural response of birds to the flooding (determine whether birds re-nested or moved after the flooding events) and behavioural response to deterrents (e.g., impacts to duration on the nest).

Although the third and final field season in 2020 was unable to proceed due to COVID-related restrictions, sufficient data was collected in 2018 and 2019 to fulfill Objectives 1 and 2, and to examine various behavioural responses of birds to deterrents. The examination of behavioural response to flooding (whether birds re-nest nearby) will be examined if feasible by the Trent/ECCC research team during field studies in 2021.

Based on the results of this research study in 2018 and 2019, the tested mitigation methods were found to be ineffective in deterring nesting birds, and their continued use was not recommended by the Trent/ECCC research team. Therefore, in accordance with the updated Migratory Bird Protection Plan (March, 2020), these measures were not implemented in 2020.

Both the FEIS for the Whale Tail Pit Project (Agnico Eagle, 2016) and the FEIS Addendum for the Whale Tail Expansion Project (Agnico Eagle, 2018) made predictions for the number of nest sites estimated to be displaced by flooding in the vicinity of the Project site. Nest displacement was re-estimated here using nesting densities observed by the research team in 2018 and 2019, along with measured peak water levels during the 2018 – 2020 nesting seasons. Based on these calculations, estimated impacts of flooding on nesting birds have been lower to date than FEIS Addendum estimates, despite changes in flood rates compared to FEIS predictions.

LIST OF FIGURES

SECTION 1 • INTRODUCTION

In 2018, Agnico Eagle Mines Ltd. (Agnico) was issued NIRB Project Certificate No. 008 the Whale Tail site, a satellite deposit at the Meadowbank Mine. Two water diversions were constructed as part of water management activities for this project, potentially impacting nesting success in shoreline areas due to flooding.

The Whale Tail Lake (South Basin) diversion (Figure 1) was initiated through construction of the Whale Tail Dike to divert flow from Whale Tail Lake and tributary lakes through waterbody A45, just south of Lake A16 (Mammoth Lake). Flooded tributary lakes include Lake A18, Lake A19, Lake A20, Lake A21, Lake A22, Lake A55, Lake A62, Lake A63, Lake A65, Pond A-P1, and Pond A-P53. In-water construction of the Whale Tail Dike was completed September 2018, and dewatering of the North Basin of Whale Tail Lake began in March, 2019. The rise in water levels from baseline (~152.5 masl) to the FEIS-predicted maximum of 156.00 masl of this area was planned to occur throughout 2019 and 2020, causing approximately 157 ha of terrestrial flooding (Agnico Eagle, 2016). In 2018, updated modeling was conducted as part of the FEIS Addendum for the Whale Tail Expansion Project (Agnico Eagle, 2018). Acquisition of higher resolution LiDAR data allowed the Whale Tail South flood predictions to be more accurate, and these calculations determined that at peak flood of 156.0 masl, 148.5 ha of terrestrial habitat would be flooded.

The Northeast diversion consists of construction of the Northeast dike to divert Lake A46 and tributary lakes through Lake C44 in the Lake C38 (Nemo Lake) watershed. Flooded tributary lakes included Lake A47, Lake A48, Lake A113, Pond A-P38, and Pond A-P68. The main construction activities for the Northeast dike were carried out from September 2018 to February 2019. Flooding of this area occurred in spring 2019, and the estimated total flooded terrestrial area was 18 ha. In 2020, the formerly flooded waterbodies in this area were fished out and dewatered to permit development of the Whale Tail Pit Expansion Project. No future flooding in this area is planned as part of the Expansion Project.

Flooding of these two areas was determined to have the potential for incidental disturbance and destruction of migratory birds and their nests. As per Nunavut Impact Review Board (NIRB) Project Certificate No.008 Condition 34, the Migratory Birds Protection Plan (the Plan) describes how these impacts are mitigated through use of visual and audio bird deterrents, and regular sweeps by personnel to discourage nesting. Mitigation was planned to be focused between 2018 and 2020, or until water levels reach their maximum flood plain.

Since the effectiveness of deterrents used in discouraging nesting was largely unknown for the resident bird species prior to 2018, a research study was initiated to assess their effectiveness and make recommendations on deterrent use during the 2019-2020 flooding. This study was developed in collaboration with Environment and Climate Change Canada (ECCC) and Trent University.

This report describes actual measured water levels during flooding to date (2019 and 2020), the mitigation measures that have been implemented according to the Plan and estimates of nesting bird displacement due to flooding. It also provides a summary of results of the Trent/ECCC research study, with the full 2020 research report provided as Appendix A.

SECTION 2 • WATER LEVELS

2.1 WHALE TAIL SOUTH

In-water construction of the Whale Tail Dike was complete in September, 2018, and dewatering of Whale Tail Lake (North Basin) began in March, 2019, initiating the planned flooding of the Whale Tail South flood zone. Dewatering was completed in May, 2020.

Maximum predicted water levels in the Whale Tail South flood zone are shown in Figure 1 (156.0 masl), along with measured peak flood levels in 2020 (155.7 masl on June 17), and post-freshet low water levels in 2020 (155.1 masl on December 27, 2020).

Due to record rainfall, peak water levels in 2019 exceeded predictions in July, but did not reach the maximum predicted final flood level of 156.0 masl. Following discussions with NWB, Agnico temporarily pumped non-contact water from the Whale Tail South (WTS) flood zone directly to Mammoth Lake, from October 21 to December 18, 2019. Construction of the South Whale Tail Channel (SWTC) to connect Whale Tail South to Mammoth Lake was complete prior to freshet in 2020. This channel now passively manages water levels in Whale Tail South.

In 2020, water levels in Whale Tail South were predicted in the FEIS Addendum to remain near the peak flood level of 156 masl following freshet. However, just prior to its' construction in early 2020, the final design of the South Whale Tail Channel was changed to reduce its inlet invert elevation by 0.5 m (to 155.3 masl), to better accommodate flood events. Operational water levels are therefore now expected to be lower than the 156.0 masl prediction.

The progression of flooding (measured water levels) is shown in Figure 2 and 3, in relation to FEIS Addendum predictions. Figure 2 shows the long-term trend in predicted water levels in relation to available baseline, dewatering- and operations-phase measurements. However, it is noted that FEIS-predicted water levels were calculated as monthly timesteps in a mean annual water balance, whereas measured water levels are assessed every 3 hours. Measured values may therefore be expected to vary around the prediction, due to both inter-annual climate variability and scale of measurement. Figure 3 more closely examines this variability for the period since flooding began (2019) and demonstrates in particular how the very rapid flood peak that is observed during freshet with multiple daily water level measurements is substantially smoothed when monthly means are plotted for better comparison with predictions.

The anticipated impact of the observed annual water level variations on predictions for nest displacement is further discussed in Section 4.

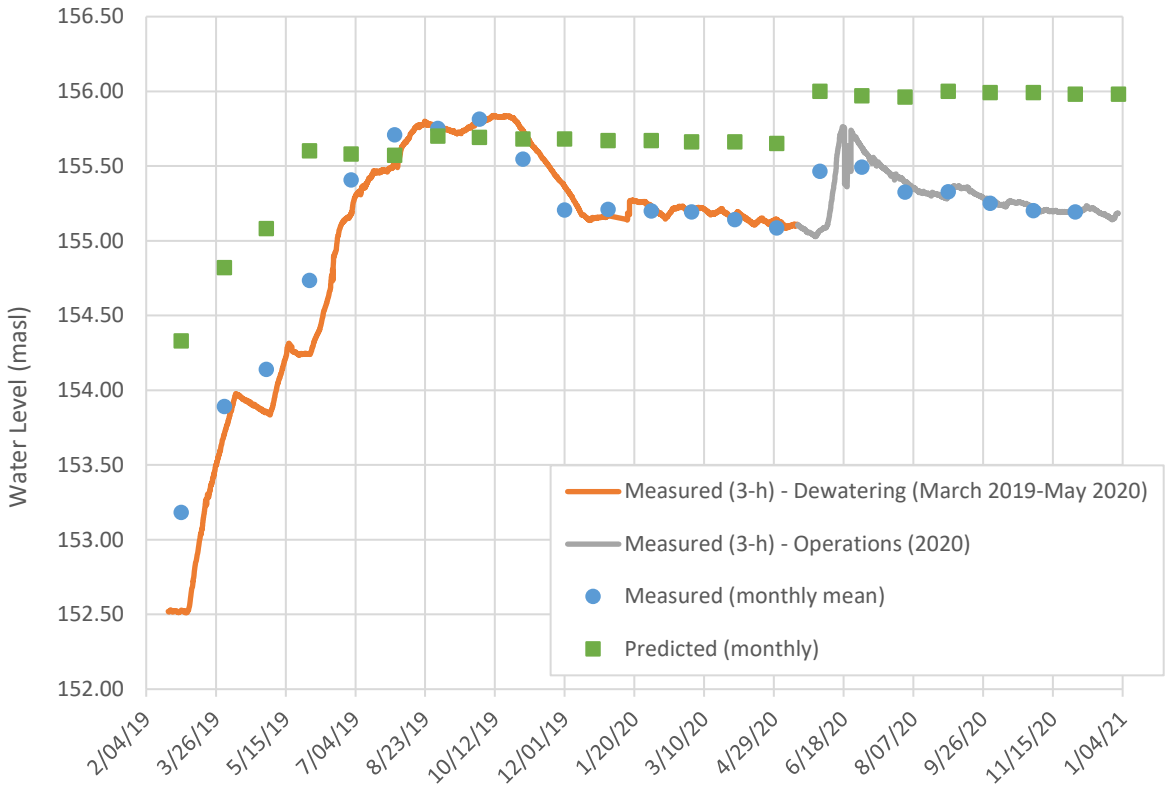

Figure 3. Measured (3-h interval and monthly mean, as indicated) and predicted water levels in the Whale Tail South flood zone. Predicted water levels from FEIS Addendum for the Whale Tail Pit Expansion Project, Appendix 6-O, Table D-14. Monthly mean water levels are shown for the months of May, June, July and August, 2020, and plotted by the month start date.

2.2 NORTHEAST DIVERSION

The Northeast Dike was constructed from September 2018 to February 2019. Maximum FEIS-predicted water levels in the Northeast flood zone are shown in Figure 3, along with measured peak flood levels in 2019, and final water levels (December, 2019). Original Whale Tail FEIS (Agnico Eagle, 2016) water management plans indicated that this flood water would increase to the maximum elevation of 156.6 masl, and then flow naturally through a tundra pond system to Nemo Lake. The maximum predicted flood level in this area (156.6 masl) was reached on July 6, 2019. At that point, it was observed that the topography toward Nemo Lake would not allow water to overflow naturally before overtopping the dike liner. As a result, following approval by NWB (see 2019 Annual Report for further details), non-contact water was pumped out of that area beginning in July, 2019, to maintain safe water operating levels against the Northeast Dike. Water was pumped from July to October 2019, and June to July 2020 towards the watershed of Nemo Lake.

Waterbodies in this area were then fished out and dewatered to permit construction of the Whale Tail Pit Expansion Project (IVR Pit area), and the Northeast Dike was dismantled. This area will undergo mine development activities, and no future flooding is planned.

SECTION 3 • MITIGATION MEASURES

According to the Migratory Bird Protection Plan (Version 1; July, 2018), the following mitigation measures were planned to be implemented in 2018 and 2019 to deter nesting of waterbirds in the Whale Tail Lake and Northeast water diversion areas during flooding:

- Deploying visual and audio bird deterrents,
- Regular sweeps by Agnico Eagle staff to discourage nesting through human activity, and to move the visual and audio deterrents;
- While Agnico may in the future consider the feasibility of using habitat modification or exclusion techniques within the flood zone in consultation with ECCC and academic institutions, these methods are not part of the primary mitigation plan.

In the 2018 nesting season, no flooding had yet occurred, so no measures were implemented.

During the 2019 nesting season, mitigation measures were implemented in collaboration with academic partners at Trent University. The crew from Trent University deployed audio and visual deterrents throughout selected plots within the Whale Tail South flood zone (Appendix A) between June 16 and 17, 2019. These were the earliest dates logistically feasible, based on weather conditions (primarily the need to wait for snowmelt). At this time, water levels were at 154.68 masl in Whale Tail South Basin, or approximately 2 m above baseline levels. Deterrents consisted of 20 x 20 m flash tape grids, and audio deterrents. Flood-zone plots were surveyed every four days between June 16 and July 14, for a total of 148 hours of sweeps within the flood zone during the 2019 nesting season. No deterrents were deployed within the Northeast flood zone, since water levels were already near their maximum predicted elevation (156.6 masl) at the beginning of the nesting season (156.3 masl on June 14, 2019).

In March, 2020, the Migratory Bird Protection Plan was updated (Version 3) according to the results of the Trent/ECCC research study in 2018 and 2019. The tested methods were found to be ineffective in deterring nesting birds, and their continued use was not recommended by the Trent/ECCC research team. Therefore, in accordance with the updated Plan, and because flooding was identified to be near complete in 2019[1], these mitigation measures were not implemented in 2020.

SECTION 4 • ESTIMATED NEST DISPLACEMENT

As described in the Whale Tail Pit Project FEIS (Agnico Eagle, 2016), a total of 10 waterbird nests and 88 upland bird territories were predicted to be displaced by flooding of 176 ha in the Whale Tail South and Northeast Diversion areas combined, if no mitigation was undertaken (TEMP Version 5, June 2018;

[1] Agnico Eagle response to ECCC Comments on the 2019 Annual Report to the NIRB (August 21, 2020). Available through the NIRB Public Registry (ID 331212).

Appendix F, Section 2.1). This prediction was made by extrapolating data from limited shoreline surveys conducted in 2015/2016 (98 nests/1.76 km^2 = 56 nests/km^2 or 0.56 nests/ha).

Updated assessments in the FEIS Addendum (Agnico Eagle, 2018) refined the estimate for the Whale Tail South flood zone as shown in Table 1. A total of 89 nests, or 0.6 nests/ha in 148.5 ha of flooding were expected to be displaced based on a maximum water elevation of 156.0 masl in 2021 (86 nests by 2020). No impacts were predicted for the Northeast Diversion area, since flooding of this area was no longer planned under the Whale Tail Expansion Project. Since flooding of this area did occur in 2019 under the Whale Tail Pit Project, prior to permitting of the Expansion Project, estimates of nest displacement made here for both diversion areas combined are conservatively compared to FEIS Addendum predictions for total nest displacement. The progression of flooding in each area and updated calculations for total nest displacement are further discussed below.

Table 1. FEIS Addendum predictions for change in flooded area and number of displaced nests in the absence of mitigation (from Agnico Eagle, 2018; Table 5.5-11). Under this Project, flooding was only planned for the Whale Tail South area. However, since flooding of the Northeast Diversion did occur in 2019, updated total nest displacement includes both flood zones.

Nesting Year	FEIS Addendum Predictions			Updated Calculations	
	Predicted Change in Flooded Terrestrial Area (ha)	Annual Additional Nest Displacement from Sequential Flooding	Total Nest Displacement	Annual Nest Displacement	Total Nest Displacement
2018	2.24	3	3	0	0
2019	+108.26	+62	65	+23-46	23 – 46
2020	+34.66	+21	86	+9 - 16	32 - 62
2021	+3.34	+3	89	-	-
2022	+0	+0	89	-	-

Estimates of nest displacement were updated for 2018 – 2020 (Table 1) based on nest densities observed by the University of Trent/ECCC research team in 2018 and 2019 (0.31 and 0.16 nests/ha, respectively – see Section 5.3.2) and measured peak water levels during each nesting season of May - August. Flooded terrestrial areas for measured water elevations were determined from FEIS Addendum modelling (Appendix 6-F).

In 2018, no flooding occurred so no nests were displaced.

In 2019, dewatering of Whale Tail North was initiated, and flood levels for the Whale Tail South area reached a maximum of 155.8 masl during the nesting season (May – August), flooding approximately 129.5 ha compared to 2018 baseline water levels (152.5 masl), and displacing an estimated 20.7 – 40.1 nests at the nest density rate of 0.16 – 0.31 nests/ha observed by the Trent/ECCC research team. For the Northeast Diversion area, peak flood occurred during the nesting season on July 6, 2019 (156.7 masl), flooding approximately 18 ha and displacing an estimated 2.7 – 5.6 nests based on the nest density observed by the research team. It is noted however that the estimates of nesting density in 2018 and 2019 were for the Whale Tail South area, and no updated estimates were conducted for the Northeast Diversion area. In total, 23 – 46 nests are estimated to have been impacted by flooding in 2019, assuming the applied mitigation measures (nesting deterrents) were ineffective and displaced birds were not able to successfully nest outside the flood zone.

In 2020, dewatering of waterbodies to Whale Tail South continued until May, but volumes were limited compared to 2019. Flood levels in Whale Tail South were at 155.1 masl prior to initiation of the nesting season (May 15[2]). They peaked during the nesting season at 155.7 masl on June 17. This degree of fluctuation in water levels appears to be within natural variation (2015 baseline measurements varied by 0.8 m within the year – Figure 2), and may be expected to continue annually. However, since some dewatering of Whale Tail North did occur in 2020 and for consistency with the FEIS schedule of predictions, impacts to nests of the 2020 flooding during freshet are calculated here. The rise in water levels from 155.1 masl on May 15 to a peak of 155.7 masl on June 17 is estimated to have flooded approximately 52 ha, displacing an estimated 8.3 – 16.0 nests. In the Northeast flood zone, water level measurements did not begin until near ice-off (June 12). From this date, however, no increase in flood levels occurred, as water levels were maintained during June and July for operational purposes, and then this area was dewatered to permit construction of the IVR pit.

Based on these calculations, impacts of flooding on nesting birds to date (Table 1; up to 62 nests) appear to have been lower than FEIS Addendum estimates (up to 86 nests), despite some changes in flood patterns compared to FEIS predictions. FEIS Addendum estimates for nest displacement assumed no mitigation was implemented (Agnico Eagle, 2018; Table 5.5-11), and that mitigation plans would be confirmed in consultation with ECCC. This consultation lead to development of the Trent/ECCC research study, through which audio and visual deterrents were deployed for testing throughout selected plots within the Whale Tail South flood zone during the primary flood season (2019). Through this study, these deterrents were later determined to be largely ineffective (see Section 5.3.1).

These estimates of nest displacement do not differentiate between nests that are lost directly from inundation and potential losses due to territory flooding, and therefore are useful for providing a conservative estimate of impacts. However, final estimates of the number of nests lost due to flooding through direct inundation are still being calculated by the Trent/ECCC research team. These results, along with the analysis of behavioural response to flooding (whether birds re-nested or moved after the flooding events, to be evaluated in 2021 via field studies by the research team, if feasible), will provide a further indication of the actual impacts of flooding on the local breeding bird population.

SECTION 5 • RESEARCH STUDY SUMMARY

5.1 INTRODUCTION

In order to determine the effectiveness of mitigation methods aimed at reducing impacts of Whale Tail site flooding on waterbirds, Agnico is conducting a 3-year study in partnership with Environment and Climate Change Canada (ECCC) and Trent University. Through this project, Agnico is also contributing to advancing the scientific understanding of conservation methods for at-risk species.

The objectives of the research study are primarily to:

1. Determine the efficacy of various audio and visual deterrents for preventing flood-zone nesting.

[2] FEIS Addendum Appendix 6-F indicates the migratory bird nesting season extends from May 17 – August 15.

2. Estimate the number of nests and the species composition lost due to the flooding.
3. Examine the behavioural response of birds to the flooding (determine whether birds re-nested or moved after the flooding events) and behavioural response to deterrents (e.g. impacts to duration on the nest).

5.2 METHODS

5.2.1 2018 Field Studies

A complete summary of 2018 field studies prepared by the research team from Trent University was provided in the 2018 Migratory Bird Protection Report.

Briefly, the objectives of the 2018 field study were to collect preliminary data to assess the effectiveness of visual deterrents in changing bird behaviour during nesting. This portion of the study was carried out at test plots without flooding along the Whale Tail Haul Road (Objective 1). Researchers also collected baseline data on nest abundance in the water diversion flood zones (Objective 2).

Objective 1 – Effectiveness of Deterrents

The field team assessed 21 plots along the Whale Tail Haul Road between the Amaruq Camp and kilometer 163 (formerly km 48) over a 6-week period, beginning June 4, 2018. Plots were chosen with the use of Ecological Land Classification maps and ground truthing. Plots are 200 x 300 meters (6 ha), covering a mix of low-lying wet sedge habitat types representative of the habitats that will be flooded around Whale Tail Lake. The purpose of the plots was to allow spatially-independent samples in which to test deterrents.

Deterrents were planned to be set up prior to bird arrival, to assess differences in nesting between sites, but delays in shipment meant they were not erected until late June. As a result, changes in behaviour of individual birds after set-up of deterrents was assessed. Due to delays in shipment of audio deterrents, their effectiveness could not be assessed in 2018.

Objective 2 – Whale Tail Flood Zone Impact Assessment

Research teams surveyed five general areas the eventual Whale Tail area flood zones over 8 days during peak incubation (June 24 – July 2, 2018). Within the North East Diversion flood zone, a total of 15 nests were found over two days of surveying and within the Whale Tail Diversion flood zone a total of 35 nests were found over 6 days of surveying (see figures in 2018 Migratory Bird Protection Report, Appendix A for locations).

Out of the 50 nests, 30 individual birds of 4 species were banded with individual markers so that they may be identified in the 2019 field season, to determine if they breed nearby once they are prevented from returning to their breeding territories by flooding.

5.2.2 2019 Field Studies

A complete summary of 2019 field studies prepared by the research team from Trent University is provided in the 2019 Migratory Bird Protection Report.

Objective 1 - Effectiveness of Deterrents

At the beginning of the 2019 study season (June 5 – 14), audio and visual deterrents were placed in the same experimental plots established in 2018 along the Whale Tail Haul Road (n = 15 plots).

Experimental plots (300 m x 200 m) were divided into two types of treatment and control plots. Treatment 1 consisted of audio deterrents playing a mix of predatory and distress calls paired with a 20 x 20 m grid of Mylar® flash tape and a Jackite© hawk kite effigy. Treatment 2 consisted of audio deterrents with the use of Jackite© (a hawk kite effigy) only. Control plots had no deterrents present.

Nest and territory densities were compared between 2018 and 2019 using a before-after control-impact design.

Objective 2 - Whale Tail Flood Zone Impact Assessment

During the 2019 field season, sixteen (16) 6-ha plots within four study locations were assessed for migratory bird presence in relation to active flooding and presence of deterrents. Deterrents were placed in the treatment plots (n = 4) within the active flood zone between June 16 – 17, 2019, and nest surveys were conducted every four days until July 14.

Objective 3 – Behavioural Responses

In 2019, monitoring was also conducted to assess behavioural responses to deterrents for the four main study species (Lapland longspur, horned lark, semipalmated sandpiper, and least sandpiper). Behavioural response metrics included territory mapping, nest fate/success, incubation duration, and distance of nesting relocation.

5.2.3 2020/2021 Field Studies

Field studies were planned to continue in 2020 as follows. However, due to COVID-related restrictions, this field season was cancelled. Analyses of data collected in 2019 by the Trent research team continued, particularly to assess observed behavioural responses to deterrents. The originally planned 2020 field study is described below. This work will be completed in 2021 by alternate research team members from Trent University, if feasible, depending on personnel availability and COVID-19 restrictions:

Objective 3 - Behavioural Responses

The study will continue to determine the re-colonisation time of nest densities in the flooded area post-flooding. This will require the monitoring of the 16 plots within the flood zone surrounding Whale Tail Lake. The project is interested in visiting the 16 plots within the flood zone to determine nest densities post-flooding, and to understand how nesting birds react the elimination of previously suitable habitat. Another focus will be to determine how bird densities change between years as the water line moves, and how elevation factors into the selection of nest sites. This will be accomplished by visiting at least 8 of the plots, located on the Eastern shore of Whale Tail Lake and its tributaries (WT1 and WT2).

5.3 RESULTS

5.3.1 Objective 1 – Effectiveness of Deterrents

Complete results describing the effectiveness of the tested deterrents are provided in Appendix A. These results demonstrate that the deterrents had limited success in dissuading birds from nesting, were relatively cost- and labour-intensive, and posed possible risks to other wildlife from entanglement.

As a result, continued use of the deterrents was not recommended for the Whale Tail site.

5.3.2 Objective 2 - Whale Tail Flood Zone Impact Assessment

During the 2018 survey of the Whale Tail study area, a density of 0.31 territories/ha was observed, with an average initiation date of June 16. Upon arrival at the Whale Tail sites in 2019, a vertical shoreline loss of 40 m (or about 1/3) of terrestrial land for plots within the planned flood zone was estimated, which occurred as a result of Whale Tail North dewatering and flood initiation in late winter. Because of this, about half of the proposed flood area plots were under water prior to the nesting season. In 2019, control plots adjacent to the flooded plots had an average density of 0.156 territories per ha. The densities in the control plots surrounding Whale Tail Lake thus decreased by 0.109 territories per ha between 2018 (pre-flooding) and 2019 (post-flooding).

During the flooding, 6 nests of 3 species were documented as lost due to direct impacts of the high water (an average minimum loss of 0.038 nests per ha). A maximum loss of 0.197 nests per ha was estimated based on the original estimated density of 0.31 territories per ha. Despite the nest loss due to flooding and a significant amount of habitat loss, nests found within the proposed flood zone plots had an estimated nest success rate of 56% in 2019.

Direct nest loss due to flooding using measured water levels is still being calculated by the Trent/ECCC research team and results will be provided in subsequent annual reports.

5.3.3 Objective 3 – Behavioural Responses

Behavioural responses of nesting birds to deterrents were assessed using temperature probe data collected in 2019. Results from temperature probe data suggested that, after controlling for environmental and temporal variation in incubation behaviour, birds exposed to deterrents had a significantly increased frequency of breaks in incubation (“off bouts”) compared to birds in control plots, but no difference in the total proportion of time spent off the nest per 12 hour period (i.e., more and shorter incubation recesses). This suggests that birds in treatment plots were disturbed and pushed off their nest more often than birds nesting in control plots. However, despite these behavioural responses to disturbance from the deterrents, birds did not abandon nests, nor was their nest success impacted in comparison to birds nesting in control plots.

Behavioural responses of birds to flooding (distance of displacement) will be assessed by the research team if feasible in 2021, depending on availability of personnel and restrictions related to COVID-19.

5.4 CONCLUSION

In summary, this project demonstrated that Arctic-nesting birds are not easily discouraged from nesting in their preferred locations and show limited responses to visual and audio deterrents. Based on the limited success, the cost of the equipment and the labour required to deploy and maintain, these methods were not recommended for mitigating nest loss in the future.

This research will culminate with a four-chapter MSc dissertation by Gill Holmes at Trent University, expected to be completed by May 2021, including the outstanding assessment of direct nest loss.

The final objective to assess behavioural response of birds to flooding will be completed by the research team in 2021 if feasible (depending on personnel availability and restrictions under COVID-19).

APPENDIX A

List of Appendices

Introduction

Mining and other forms of resource development frequently result in disturbance to wildlife that is difficult to avoid. Technological options to mitigate these impacts are therefore of great interest to resource developers and conservationists alike. Mining is an important economic driver in the north by providing jobs for people living in northern communities (Cameron and Levitan 2014; Belayneh et al. 2018). In Nunavut alone, 18% of the gross domestic product in 2014 was associated with resource extraction (AMAP 2017). Mineral, oil and gas exploration is expected to increase throughout the Arctic landscape (A.T. Kearney Inc. 2015), leading to land use changes and disturbance of important habitat for wildlife (Wilson et al. 2013). Resource extraction can have detrimental impacts on habitat quality through the modification of landscapes, increased pollutants, and human disturbance (Reijnen et al. 1997; Johnson et al. 2005; Hassan 2016). Studies from Hof et al. (2017) have demonstrated that arctic-nesting birds are especially vulnerable to climate change; with the increase of resource extraction in arctic landscapes leading to additional loss in nesting habitat there is an even greater probability of future species loss (Gajera et al. 2013; Bernath-Plaisted and Koper 2016). Finding a balance between conservation and economic growth is crucial in vulnerable landscapes such as the Arctic, particularly when faced with climatic change (Wauchope 2016).

This report outlines progress made on the Waterbird Mitigation Project during 2020. As for most researchers around the world, our **2020 field season was cancelled due to the Covid-19 global pandemic.** Nevertheless, we were able to make significant progress on analysis and interpretation of results regarding the efficacy of bird deterrents.

Project Overview

Agnico Eagle Mines Ltd. is currently developing the Whale Tail Project, approximately 130km North of Baker Lake, NU. The project included the construction of two dykes within the northern portion of Whale Tail Lake that diverted water from the Whale Tail mining pit into the surrounding lakes and tributaries. This resulted in flooding that elevated the water levels by 4 m above current levels over two years between 2019 and 2020, flooding approximately 157 ha of tundra during the breeding season for arctic birds. The Migratory Birds Convention Act (1994) prohibits the harm of migratory birds and the disturbance or destruction of nests and eggs. Therefore, the company is committed to avoiding or minimizing this harm and developing mitigation strategies.

As part of a collaboration between Trent University, Environment and Climate Change Canada and Agnico Eagle Mines Ltd., this project explored mitigation options for flooding during the construction phase of the Whale Tail Pit. Mitigation options sought to deter birds from nesting in high risk areas, so that the impacts from mining-induced flooding or other localized disturbances could be minimized.

Through the use of both experimental and observational approaches, the objectives of the research were to (1) determine the most effective bird deterrents and the manner in which these deterrents should be applied, (2) assess the degree of risk posed to nesting migratory birds by mining-induced flooding and estimate the number of nests and the species composition lost due to the flooding and (3) examine the behavioural response of birds to the flooding, to determine whether birds re-nested or moved after the flooding events.

Year Two - 2019 Overview

The 2019 field season began on May 23rd with the arrival of Gill Holmes (MSc. Candidate) and technician, Sophie Roy. Late May tasks included assembling the audio deterrents and troubleshooting problems that arose in the field, testing visual deterrents in the field and preparing the other equipment required for the season. Three more technicians arrived on the 1st of June and 3rd of June including Amy Wilson, Joanne Hamilton and Sarah Bonnett.

When the crew arrived on site, flooding had already occurred. Although Whale Tail Lake was frozen, there was a drastic change in the riparian zone edge due to the late winter flooding of Whale Tail Lake's southern basin. Snow melt occurred in the first week of June, with an unexpected snowstorm on the 9th of June, blanketing the landscape with an estimated 8 cm of snow. Whale Tail Lake began to thaw between early- and mid-June, revealing signs of water level changes on the land (Figure 1).

Figure 1: Examples of the shoreline flooding due to the diversion into the southern basin of Whale Tail Lake. Top: A view ground view of the flooding at Whale Tail Three site, Amaruq Mining Camp in the background. Bottom: An above view of the flooding at Whale Tail Three site. Please refer to Figure 4 for detailed map of the Whale Tail site.

Deterrents were deployed between 6 and 17 June, slightly later than planned due to late arrival of gear and the heavy snow on 9 June. The field crew departed the site on 19 July, for a field season length of 57 days.

Methods

Objective 1. Efficacy of Deterrents

Deterrents were tested through a Before-After Control Impact experimental design, carried out along the Amaruq Road. A total of 15 plots (300 m x 200 m) were established during 2018 within 1 km of the Amaruq Road, between the 5 - 14 June (Figure 2). These plots were selected as 5 groups of three, with each group containing two treatment plots (High Intensity Treatment and Low Intensity Treatment, Table 1) and one control plot. In 2018, no deterrents were applied, representing the "before" phase of the experimental design. In 2019, the High Intensity Treatment consisted of audio deterrents playing a mix of predatory and distress calls paired with a Jackite© predator effigy placed in the centre of the plot, and Flash Tape grid covering the entire plot, with tape deployed every 20 m in both directions (Table 1). The High Intensity Treatment was chosen to potentially be the most effective at deterring breeding birds, but was also the most labour-intensive. The Low Intensity Treatment consisted of audio deterrents and an effigy only, and was selected as a less labour-intensive option (Table 1). Control plots contained no deterrents.

Were made repeated visits to the plots to map out the locations of territorial birds, and to attempt to find all nests. For mapped territories, we calculated the proportion of the territory within each plot. In cases nests were found but territories could not be mapped, we assumed that the territory was centred on the nest and had a size equal to the average territory size for the species in our data. We compared territory densities in control and treatment plots between years using a linear mixed-effects model (lmer in R), with Year, Treatment and their interaction as fixed effects. In this BACI design, the deterrents are effective at reducing birds' nesting densities if there is a statistically significant interaction effect

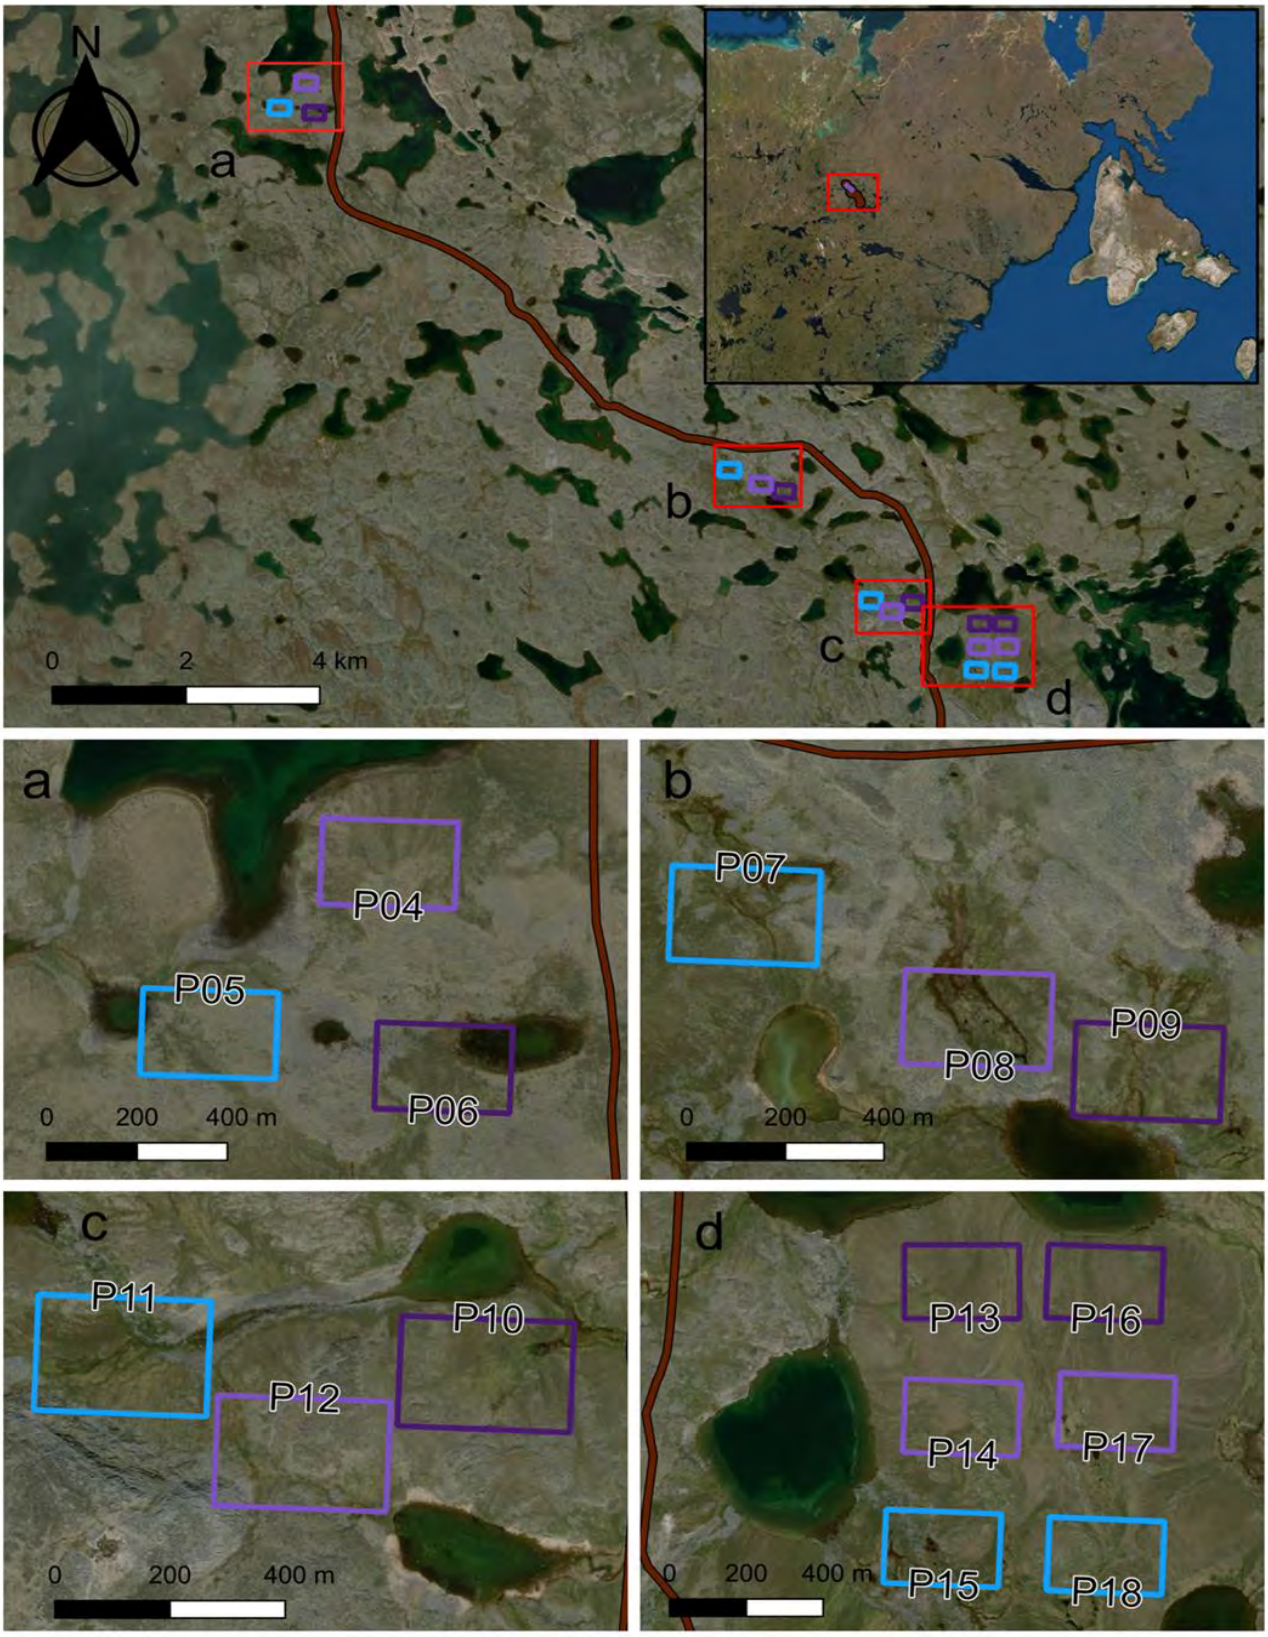

Figure 2: Map of study site Amaruq Road sites located north of Baker Lake, Nunavut along Amaruq Road between Amaruq Mine and Meadowbank Mine run by Agnico-Eagle Ltd. Top map shows the general study area, while the bottom four panels show the five groups of three plots, with dark purple representing High Intensity Treatment, light purple representing Low Intensity Treatment and light blue representing the Control. The site is split by location, with five separate clusters; (a) Cluster One includes plots 4, 5 and 6, (b) Cluster Two includes plots 7, 8, and 9, (c) Cluster Three includes plots 10, 11, and 12, and (d) Cluster Four, includes plots 13, 14, 15, and Cluster Five includes plots 16, 17, and 18.

Table 1: Description of the three treatment types deployed within the plots located within two study sites; the Amaruq Road Sites and Whale Tail Sites. Details include an outline of equipment, description of use, and frequency of use.

Treatment Name	Location	Deterrents Use
High Intensity Treatment	Amaruq Road Sites	• Audio Deterrents: "Super BirdXpeller ® PRO" by Bird-X, Inc. Speakers broadcasting all at once with recordings played randomly in non-sequential order, continuously for 24 hours at 10 - 30-minute intervals. • Hawk Effigy: "Peregrine Falcon Kite" by Margo Supplies. • Flash tape Grid: 20x20m grid.
Low Intensity Treatment	Amaruq Road Sites	• Audio Deterrents: "Super BirdXpeller ® PRO" by Bird-X, Inc. Each speaker broadcasting one at a time with recordings playing in sequential order continuously for 24 hours at 5 - 10-minute intervals. • Hawk Effigy: "Birds of Prey Falcon Kite" by Sutton Agricultural Enterprises. • Flash tape Grid: None
Treatment	Whale Tail Sites	• Audio Deterrents: "Super BirdXpeller ® PRO" by Bird-X, Inc. Speakers broadcasting all at once with recordings played randomly in non-sequential order, continuously for 24 hours at 10 - 30-minute intervals. • Hawk Effigy: None • Flash tape Grid: 20x20m grid.

between the treatments and years, with 2019 (post-treatment) showing lower densities in the treatment plots but not the controls. Because plots were selected in groups of three, we added a random effect for group to the model to account for potential non-independence. We also included the number of hours spent nest searching and monitoring in the plots, as an offset to account for variable search effort. This offset accounts for potential bias that might have arisen because we spent more time in plots assigned as High Intensity Treatment than in other plots, because of the frequent need to maintain the deterrents. We conducted analyses on the following groups of birds: All four study species combined (Figure 3), shorebirds only (Semipalmated Sandpiper, *Calidris pusilla*; and Least Sandpiper, *Calidris*

minutilla) and individually for Lapland Longspur (*Calcarius lapponicus*) and Horned Lark (*Eremophila alpestris*). We excluded all other species with much lower rates of encounter from the analyses of male territory density.

Figure 3: Four main study species, left to right; Lapland Longspur, Horned Lark, Semipalmated sandpiper, Least sandpiper.

Objective 2. Flood Zone Impact Assessment

During the 2018 field season, the predicted flood site (Figure 4) was surveyed for nests between 24th and 25th of June and 29th June – 2nd of July for a total of 40 search hours. These surveys were conducted to obtain an estimate of the densities of breeding birds that would be exposed to the flooding event. The dates were towards the end of the nesting season, later than ideal, due to limited access to the sites. After the initial survey, we divided the Whale Tail site into four main flood zone areas (Figure 5). These areas were selected based on habitat quality (predominantly sedge meadow), and low elevation, and were most likely to support breeding birds that would be impacted by the flooding.

The 2018 survey consisted of four surveyors, each separated by 10 – 20 m, walking parallel to the edge of the lake, and within the proposed flood zone (as described in Appendix 6-F - Flooding During Phases report by Golder Associates and AEM). Surveyors walked together, while watching the ground, to observe flushing birds or other breeding activity. When a bird was observed, all surveyors stopped, and one or more surveyors attempted to find the nest by waiting for the bird to return to its nest, or by searching the area where the bird was initially observed. We used a Garmin© GPS to mark each nest found, and observations and notes were written in a field notebook. Nest locations were plotted in a

QGIS (3.16.0) to ensure that they fell within areas proposed for flooding. Nest densities around Whale Tail Lake were estimated based on nests found during the 2018 surveys, with an estimated 3.4 territories per hectare, within the proposed flood zone of 157 ha.

During the 2019 field season, the four Whale Tail site areas were divided into 2 separate plots of approximately 6 ha, with the addition of two adjacent plots outside of the predicted flood zone to be used as control plots (Figure 5). In each area, the two plots within the flood zone were assigned to either a deterrent treatment, or a no deterrent treatment. The deterrent treatment included a flash tape grid and audio deterrents. Deterrents were placed in the treatment plots (n = 4) between the 16 -17 June 2019. Plots outside the flood zone were considered control plots, with no deterrents applied and no flooding occurring. Whale Tail site plots were surveyed every four days, between the 16 June - 14 July, for a total of 148 search hours within the proposed flood zone and adjacent control plots.

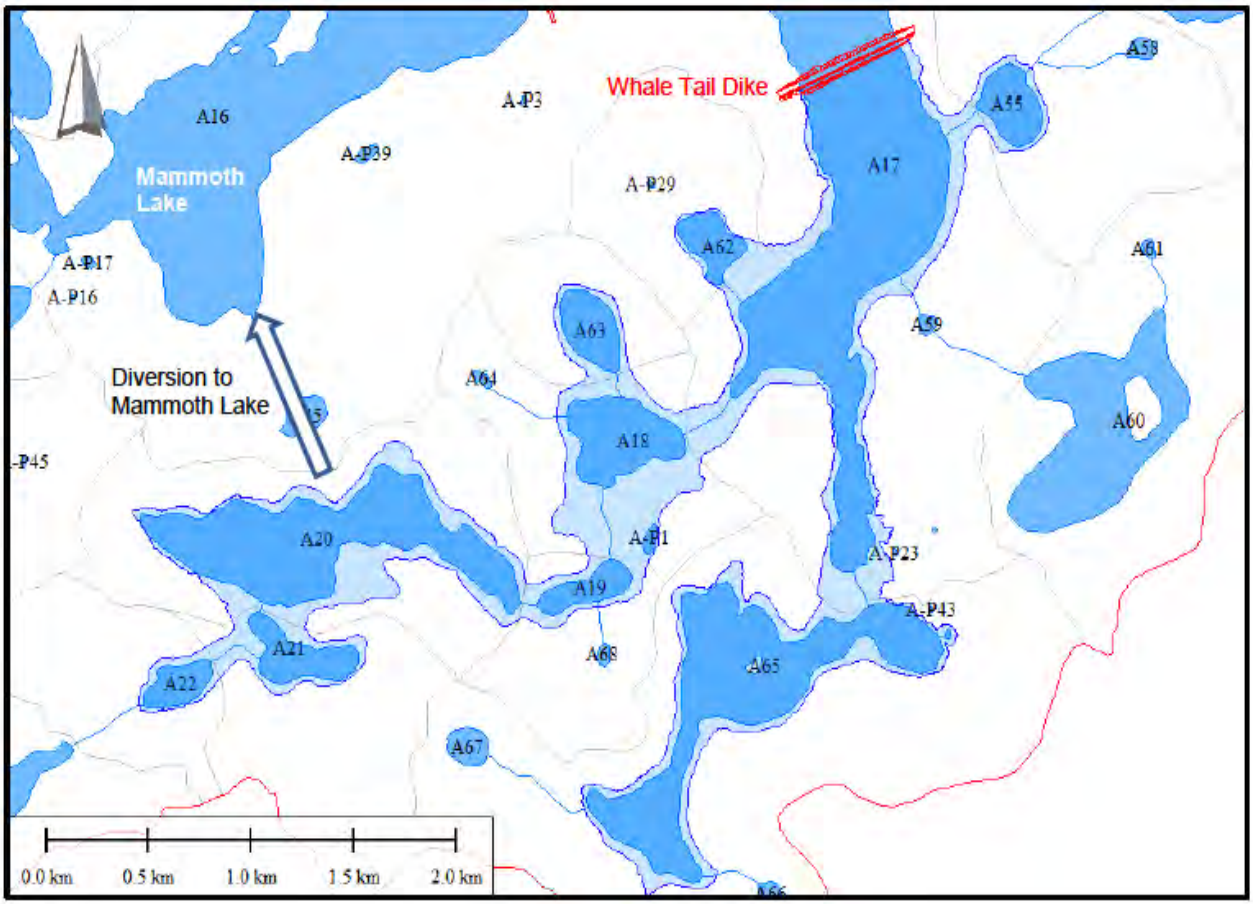

Figure 4: Map of Whale Tail Lake and its adjacent lakes and tributaries including the boundary of the proposed flood area in light blue. Taken from Golder Associates and Agnico Eagle Ltd. June 2016 Vol. 6 Freshwater Environment Report, Appendix 6-F, Flooding During Phases.

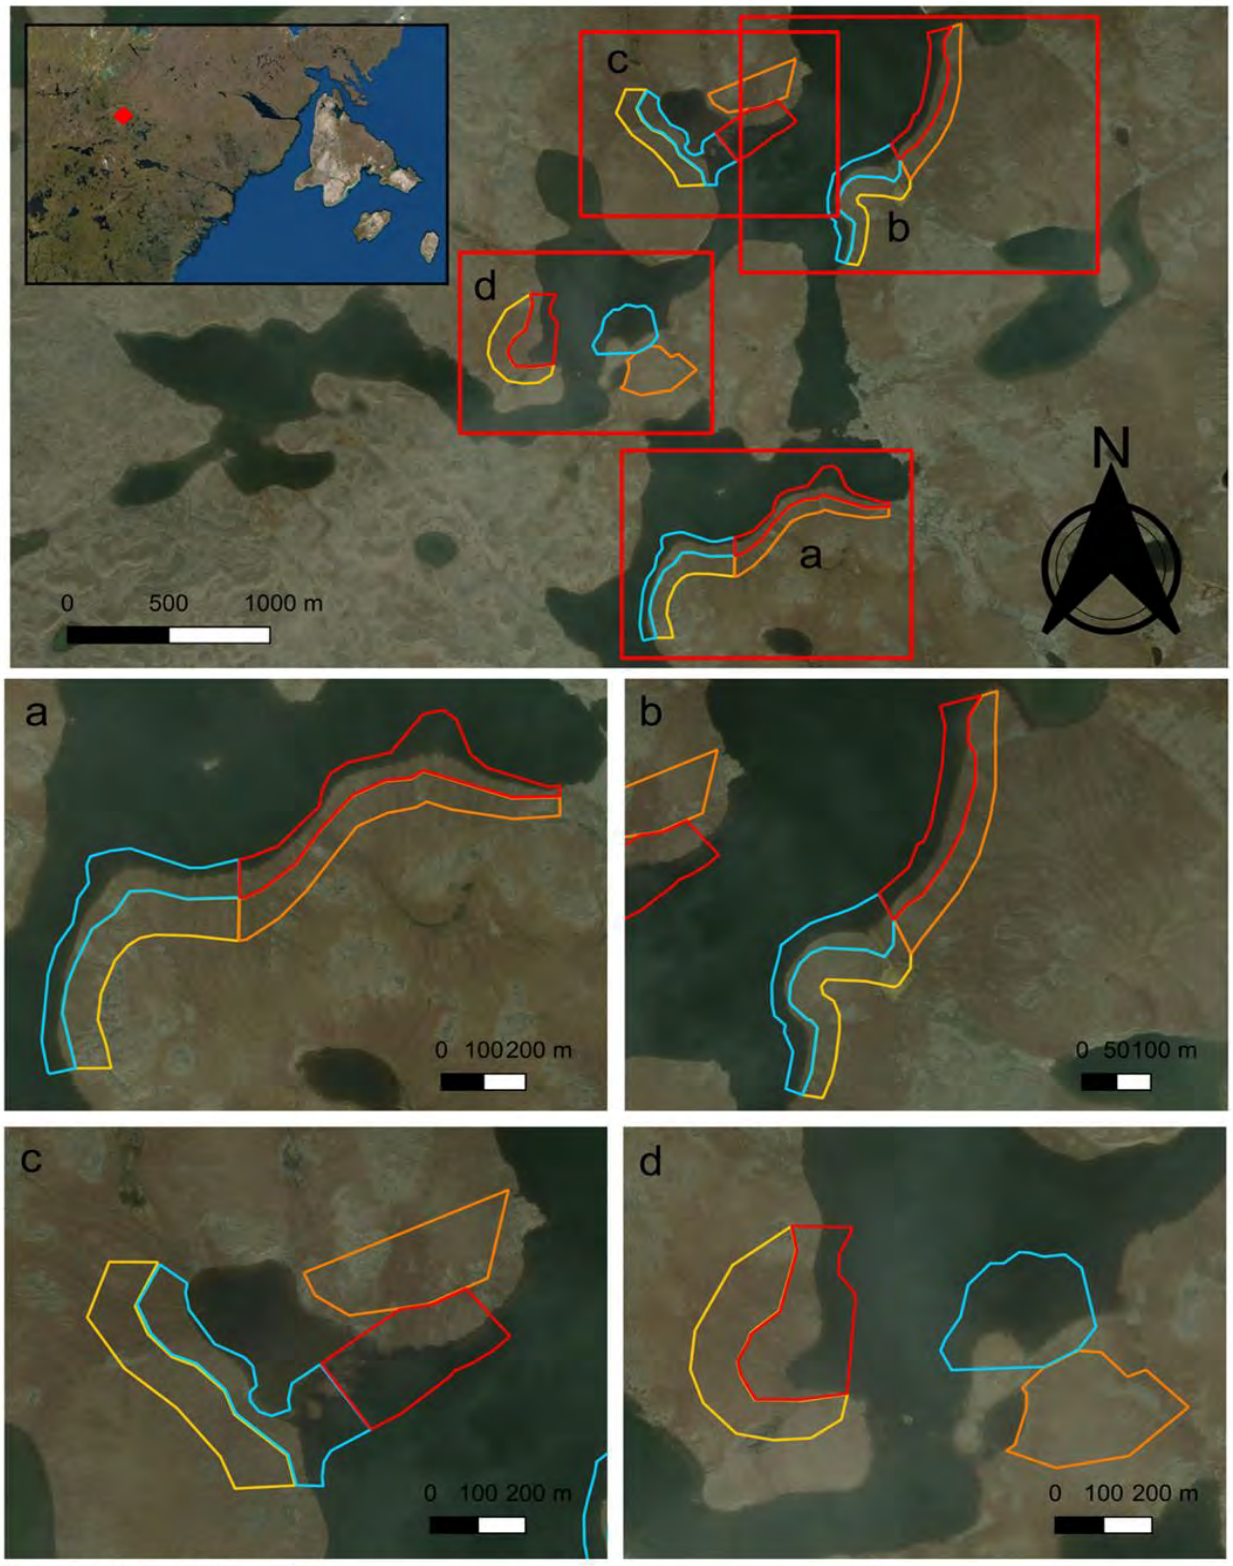

Figure 4: Map of study site Whale Tail Flood Area located north of Baker Lake, Nunavut, part of the Amaruq Mine and includes Whale Tail Lake and its tributaries. Top map shows the general study area, while the bottom four panels show the four groups of four plots, with red representing Treatment, blue representing Flood Control, yellow representing Control One, and orange representing Control Two. Sites are grouped into clusters based on treatment plots, (a) Whale Tail One, (b) Whale Tail Two, (c) Whale Tail Three, (d) Whale Tail Four. Source map is taken post-flooding of the southern basin of Whale Tail Lake. Plot outlines indicate the terrestrial area perimeter pre-flooding in 2018.

Objective 3. Birds' Behavioural Responses to Deterrents

Nest and Territory Monitoring

Monitoring of nesting birds occurred throughout the 2019 breeding season between 6 June - 14 July, within the experimental plots and the flood zone sites. There were four main study species: Lapland Longspur (*Calcarius lapponicus*), Horned Lark (*Eremophila alpestris*), Semipalmated Sandpiper (*Calidris pusilla*) and Least Sandpiper (*Calidris minutilla*) (Figure 2). These species are the most abundant at the study sites, and the easiest species for both locating and monitoring nests, however we did monitor any nest found regardless of species. Territorial mapping occurred primarily at the beginning of the breeding season, once male birds arrived and began to sing and display. Mapping was done by observing the locations of displaying or singing males and marking the location with a waypoint using a Garmin© GPS. A minimum of 10 points were recorded during each visit to the territory.

Nest searching occurred by systematically walking plots and observing behavioural cues of breeding adults (e.g., flushing, mate courtship, alarm calls). Upon discovery of a nest, it was marked with a tongue depressor 5m from the nest in a random direction, labeled with a nest name, along with the distance and bearing to the nest from the marker. We recorded the exact coordinates of the nest using the "average waypoint" function within the GPS unit, the species, number of eggs present, and date found. Nests were visited approximately every 4 days until fates were determined. Methods to assess nest fate depended on the life history of each target species. For species with precocial young (i.e., *Calidris sp*.), nests with at least one hatched egg were considered successful, whereas for species with altricial young (i.e., Passerines), nests with at least one fledged young were considered successful. Signs of predation

(loss of a whole clutch, nest disturbance, large eggshell fragments or yolk) or abandonment (no sign of adults or cold eggs) indicated failed nesting attempts (Mabee 1997).

Twenty Lapland Longspur nests received a temperature logger to monitor patterns in incubation behaviour. Ten nests were monitored within treatment plots, and ten in control plots. Temperature logger data were screened for outliers from equipment failure, and then analyzed with the use of RHYTHYM (1.0; Cooper and Mills 2005) and Raven Lite (2.0) to determine the number of off-bouts for each individual bird. I assessed if there was a significant difference in the proportion of off-bouts and number of off-bouts within a 12 hour period between nests in treatment and control plots, with the use of a linear mixed-effects model. Covariates for time of day (day or night per 12 hour period), average ambient temperature (per time of day), nest concealment, clutch size, and stage of incubation cycle were included in the model, and these variables are all known to potentially impact incubation schedules (Camfield and Martin 2009).

Marking and Re-sighting

In 2018, birds of the four focal study species found within the predicted flood area were captured with the use of a bow net at the nest and banded with individual colour markers. By resighting these individually marked birds, we could determine whether birds banded in 2018 within the predicted flood were dispersed to nearby non-flooded areas due to flood impacts, potentially increasing the densities of birds in the adjacent control plots. Similarly, for nesting birds banded in the predicted flood areas in 2019, resighting allowed us to determine whether the disturbance from the treatment plots or the active flooding caused birds to re-nest in adjacent sites. Resighting occurred during every visit to the plots,

every four days throughout the season. We also planned to return to the study site in 2020 to re-sight previously banded individuals but were unable to due to the cancellation of field work.

We captured adults once their clutch was complete and the nest was in the incubation stage (i.e., the number of eggs in the nest was no longer increasing). We attempted to capture both members of the pair for species where both adult birds incubate (i.e., *Calidris sp*.). For species where only one adult incubates (i.e., Passerines), we captured the incubating bird, although in a few cases both adults were captured. When a bird was captured, we measured the head-bill length, tarsus length, and wing length to the nearest mm and weight in grams. All birds were banded with a standard Canadian Wildlife Service issued stainless-steel metal band that has a unique 10-digit number. In addition, Semipalmated Sandpipers received a white flag with a 3-letter alpha code, and a single plastic coloured band. Least Sandpipers received a white flag and 2 colour bands. Lapland Longspurs and Horned Larks were given a unique combination of 3 plastic colour bands. Band combinations were read from left to right as per standard protocol and were recorded when re-sighting a previously banded bird.

Results

Objective 1. Efficacy of Deterrents

Our results suggested that deterrents did not significantly impact male territory densities for the four study species combined, nor for the shorebird species only, or for Lapland Longspur (Figure 6 a-c). There was no significant treatment*year interaction term in the models for any of these groups of species (P's > 0.05), and the tendency was for higher densities, rather than lower densities, in the year with deterrent treatments. In contrast, Horned Lark territory density was significantly reduced in the High Intensity treatment in 2019, suggesting that Horned Larks avoided plots exposed to the High Intensity

deterrent treatment (Figure 6 d). These results demonstrate that intense deterrent treatments might be successful at reducing densities for some species but are not broadly effective at deterring all bird species from establishing territories and nesting.

Cost and Maintenance of Deterrents

Deterrent deployment occurred over multiple days, taking a total of 198 person hours to deploy over 10 treatment plots, not including the extra 120 hours to assemble and troubleshoot prior to deployment. In most cases, a crew of 6 – 8 people spent 4 hours deploying the flash tape grid within a single High Intensity Treatment 6-ha plot. Deterrent maintenance was done every 4 days, with the time spent in the plot ranging from 20 mins to 4 hours, depending on damage and needs. Examples of maintenance were ensuring that the hawk kite effigy poles were erect and that the kite was still intact, ensuring the fishing line holding together the flash tape grid was taut, and ensuring flash tape was not tangled around hummocks or brush. In some cases, the deterrents were so damaged that it took hours to repair or were completely and could not be repaired. For example, on multiple occasions, the flash tape grid was destroyed when caribou or muskoxen travelled through the plot, causing the entire grid to collapse and requiring re-deployment. This re-deployment took hours, and also demonstrated a possible risk to arctic wildlife, which may have become entangled in the flash tape and fishing line.

Costs for the audio and visual deterrents were also significant. The audio deterrent units (Bird-X Super Bird X-peller Pro) cost $509.99 CAD, with 14 purchased in 2019 for a total of $7,139.06 CAD. This cost included audio chips for each audio unit ($60.00 CAD each). To keep the batteries charged, so the audio deterrents would run for up to 6 weeks, we purchased 14 small solar panels, $89.99 CAD each, for a total of $1259.86 CAD. The 12V car batteries used to run the audio deterrents and hold the solar panel charge,

were donated by Environment and Climate Change Canada. Visual deterrent costs came to a total of $5,131.25 CAD, with Hawk Kite Effigies costing $524.75 CAD for 12 Hawk Kites, with Fiber glass poles (10) totaling $517.50 CAD and replacement strings (7) $42.00 CAD. Flash tape rolls were $5.40 CAD per roll, amounting to $1,917.00 CAD for 355 rolls. Fishing line was used to string the flash tape grid together, costing $850.00 for 34 rolls of 100lb Hercules PE Braided Fishing Line, 4 Strands. Finally, the Aluminum Angle used to erect the flash tape grid, with 640 pieces of 1 m long angles, cost $1,280.00 CAD. The complete cost of deterrents for the project was $13,529.17 CAD.

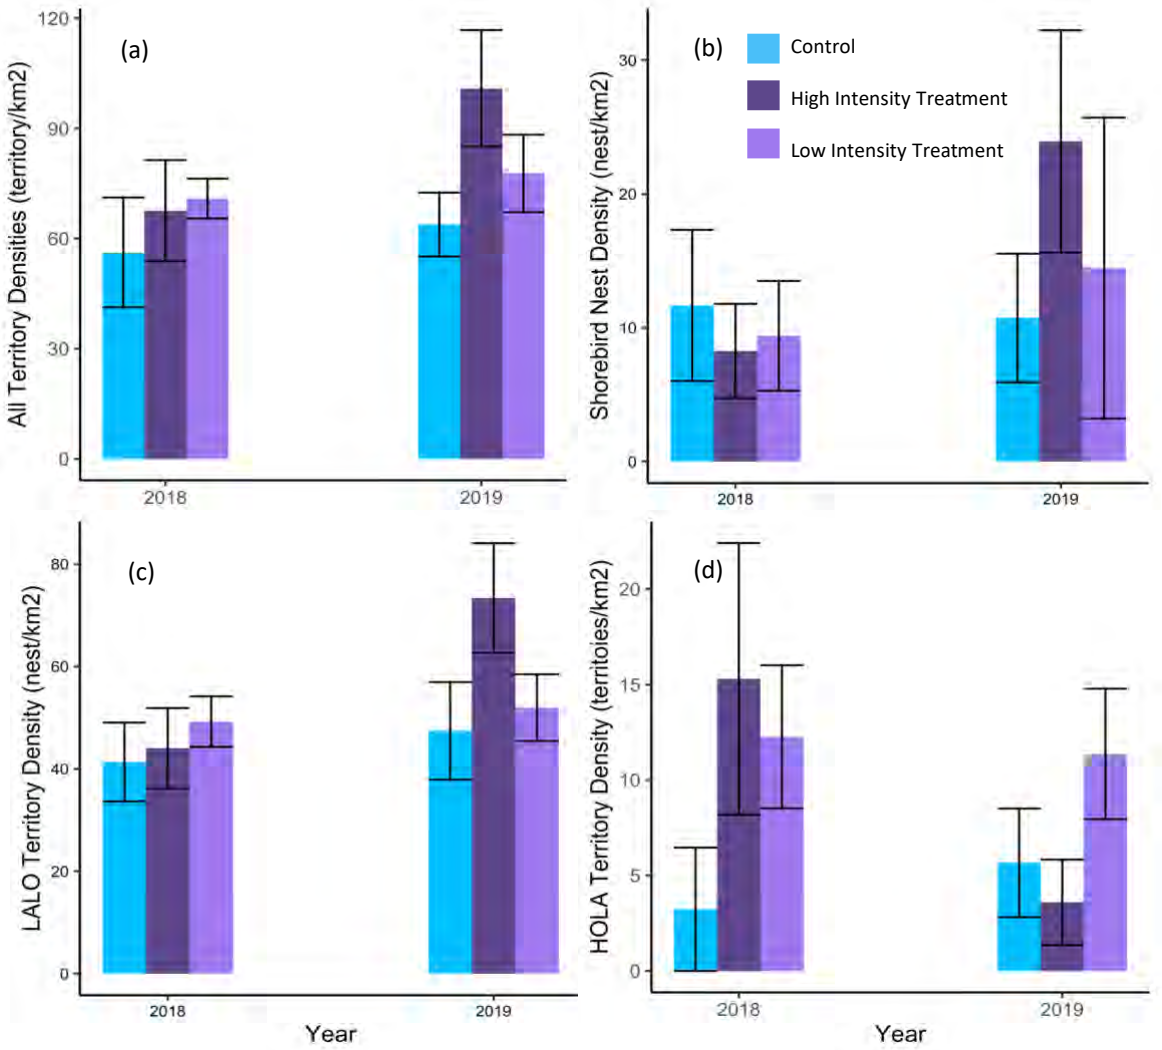

Figure 7: Male territory densities (territories/km^2 ± SE) before (2018) and after (2019) deterrent deployment of two deterrents treatments located in the Amaruq Road sites for, **(a)** All four species combined, **(b)** shorebird species only (Semipalmated Sandpiper and Least Sandpiper), **(c)** Lapland Longspur and **(d)** Horned Lark only. Please refer to Appendix III for exact mean male territory density (territories/km^2) numbers.

Objective 2. Flood Zone Impact Assessment

During the 2018 survey of the Whale Tail study area, we estimated 31 bird territories per km^2, with an average initiation date of 16 June. Given these dates, we concluded that the proposed flooding timeline outlined in Terrestrial Ecosystem Management Plan - Version 4, by Golder Associates, would flood nests along the shore of Whale Tail Lake. When we arrived at the Whale Tail sites in 2019, we estimated a vertical shoreline loss of 40 m (or about 1/3) of terrestrial land for plots within the proposed flood area, which occurred when Agnico Eagle Mines Ltd. flooded in late winter. Because of this loss, about half of the proposed flood area plots were under water prior to the nesting season. In 2019, control plots adjacent to the flooded plots, had an average density of 15.6 territories per km^2. The densities in the control plots surrounding Whale Tail Lake thus decreased by 10.9 territories per km^2 between 2018 (pre-flooding) and 2019 (post-flooding).

Figure 8: A Lapland Longspur nest with four eggs that was found within the Whale Tail Lake flood zone. It was found active, but later in the season became flooded.

During the flooding, we documented 6 nests of 3 species that were lost due to direct impacts of the high water. We estimate an average minimum loss of 3.8 nests per km^2 by taking the number of nests observed to be lost and dividing it by the total proposed flood zone of Whale Tail Lake (1.575 km^2), and a maximum loss of 19.7 nests per km^2 with an estimated density of 31 territories per km^2. The species nests that we observed to be flooded were Lapland Longspur (4; Figure 8), Semipalmated Sandpiper (1) and Herring Gull (1). Despite the nest loss due to flooding and a significant amount of habitat loss, nests

found within the proposed flood zone plots had an estimated nest success rate of 56% in 2019.

Objective 3. Bird Behavioural Responses

During the 2019 field season, 20 temperature probes were deployed in nests within the experimental treatment (n = 10) and control (n = 10) plots. Temperature probes measure birds' trips on and off the nest, which can offer a sensitive measure of disturbance. Results from temperature probe data suggested that, after controlling for environmental and temporal variation in incubation behaviour, birds exposed to deterrents had a significantly increased frequency of breaks in incubation ("off bouts") compared to birds in control plots (Figure 9), but no difference in the total proportion of time spent off

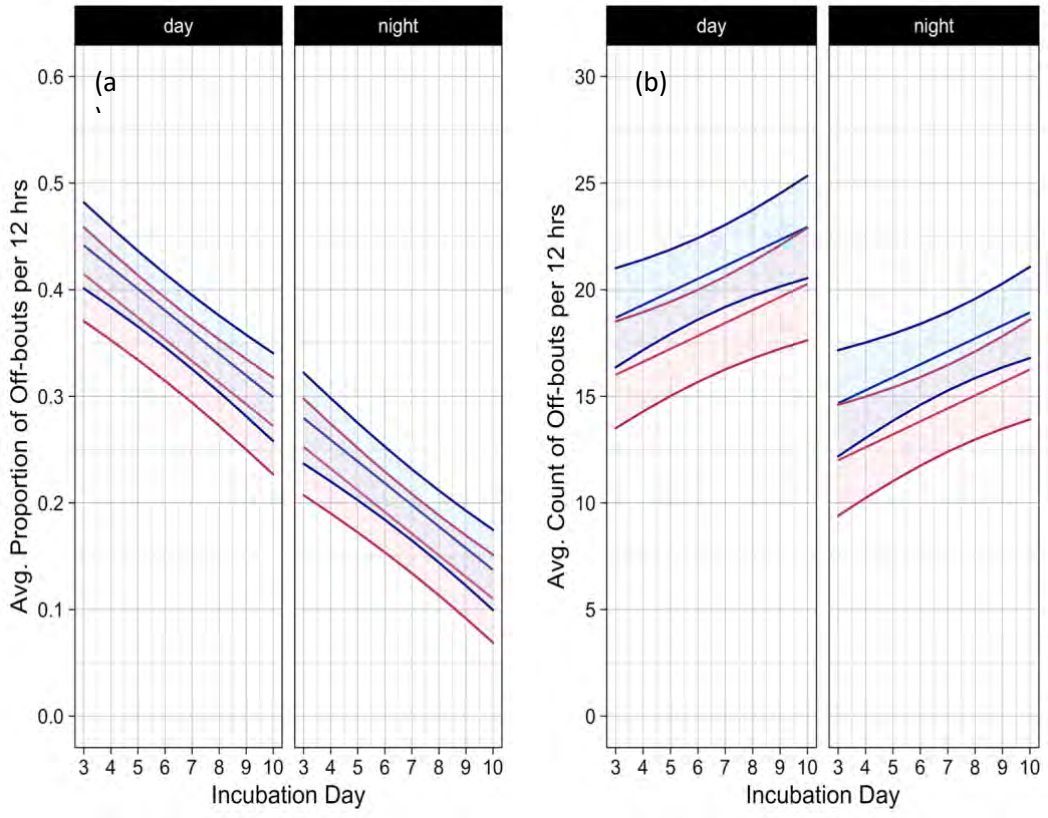

Figure 9: Predicted values from a linear model mixed effects model, with 0.95 confidence intervals, for proportion of off-bouts (a) and count of off-bouts (b) per 12 hour period split between day and night comparing nests within treatment (n = 10; blue line and fill) and control (n = 10; red line and fill) over incubation cycles from day 3 to 10.

the nest per 12 hour period (i.e., more and shorter incubation recesses). This suggests that birds in treatment plots were disturbed and pushed off their nest more often than birds nesting in control plots. However, despite these behavioural responses to disturbance from the deterrents, birds did not abandon nests, nor was their nest success impacted in comparison to birds nesting in control plots.

Birds nesting within the proposed flood zone were captured and banded with unique band combinations in both 2018 and 2019. A total of 13 female Lapland Longspur and 8 Semipalmated Sandpipers were banded in 2018, and only one Semipalmated Sandpiper was resighted in 2019, nesting in the same location as 2018. In 2019, a total of 17 female and 3 male Lapland Longspur and 13 Semipalmated Sandpipers were banded. In the same year, a single Lapland Longspur female re-nested after nest loss due to flooding, nesting approximately 125 m from the original nest and 50 to 100 m away from the proposed flood zone. The original nest was estimated to be lost during the nestling stage due to flooding between 1-3 July and we estimated that the bird initiated a new nest on 3 July.

Discussion

Based on the results of the deterrent experiment, we conclude that the deterrents deployed in this experiment had limited success at dissuading birds from nesting. Moreover, they were relatively cost- and labour-intensive to erect and maintain, relative to their effectiveness. Therefore, we do not recommend their use in future attempts to prevent nest loss of arctic-nesting birds. We are confident that the deterrents we used failed to deter birds from nesting in the flooded areas, resulting in the loss of nests due to mining-induced flooding. A small number of studies in other environments have documented the successful use of deterrents, with similar approaches to those used here. However,

several factors may have contributed to the limited success that we observed, including the birds' life history and the challenges of erecting deterrents sufficiently early in arctic environments.

Our sample is dominated by small, short-lived species such as the Lapland Longspur. These species may be especially reluctant to abandon or forego a breeding attempt in the presence of novel objects such as our deterrents, as they have fewer breeding opportunities compared to long-lived species. Previous studies have demonstrated the successful use of flash tape grids and other visual deterrents to prevent Piping Plover and Least Tern from nesting within gravel pits (Marcus et al. 2007). These species both respond to approaching predators with aggressive of evasive behaviours. In the case of our study, the placid Lapland Longspur showed no signs of obvious distress or disturbance during deterrent use. There were multiple occasions where a nest was found within 5 m of an audio deterrent speaker or directly under a piece of flash tape (Figure 10).

Erecting deterrents sufficiently early was also a challenge. The average nest initiation date in our study was the 13th of June, with the earliest initiation date estimated as the 6th June and the latest the 25th of June in 2019. Deterrents were erected 5-17th June, before 79 - 92% of nests were initiated in the plots where deterrents were deployed within the Amaruq Road Sites. Erecting deterrents this early was challenging; the frozen ground made it difficult to hammer the aluminum angle into the ground, and the melting snow made it difficult to ensure that

Figure 10: An extremely concealed Lapland Longspur nest with a piece of flash tape draped over it.

the audio deterrent speakers stayed upright. Deploying deterrents well before territories were established may have been most effective but would be even more logistically challenging. Erecting deterrents in the late winter and early spring, would mean that the extensive snow cover would obscure the location of ponds and other areas unsuitable for setting up equipment, and freezing temperatures could cause a variety of problems with icing of flash tape, battery failure and other issues.

During the experiment there were a few instances where deterrents were damaged or destroyed due to mammals. In some plots where we found Arctic ground squirrels (*Spermophilus parryii*) or Arctic hare (*Lepus arcticus*) we anticipated that there might be some damage to the wires associated with the audio deterrent units. Damage by Arctic ground squirrels occurred on one occasion when a speaker cord was chewed, but we noticed and replaced the cord quickly. A more concerning issue arose as there was some noticeable impact on large ungulate species such as caribou and muskoxen. There were multiple occasions where visual deterrents were destroyed by caribou or muskoxen walking through the treatment plots, causing aluminum poles to be ripped out of ground and carried away. There was a case where fishing line was found to have blood on it, possibly from a caribou who may have got the fishing line caught around their mouth. These concerns warrant investigation, perhaps through the use of time-lapse cameras near flash tape grids. And caution should be used if flash tape is to be deployed in areas frequented by large mammals.

In summary, our project demonstrates that arctic-nesting birds are not easily discouraged from nesting in their preferred locations and show limited responses to visual and audio deterrents. Based on the limited success, the cost of the equipment and the labour required to deploy and maintain, we would not recommend these methods for mitigating nest loss in the future. Plans for the project sought to

monitor the Whale Tail Lake site post-flooding to assess nest and territory density changes due to the terrestrial area's flooding. However, this was not completed in 2020 due to the Covid-19 pandemic and will not continue into the 2021 season and onward. This research will culminate with a four-chapter master's dissertation by Gill Holmes at Trent University, expected to be completed by May 2021.

Hunter Harvest Survey

MEADOWBANK MINE

2020 HUNTER HARVEST STUDY AND CREEL SURVEY SUMMARY REPORT

FINAL

Table of Contents

List of Tables

List of Figures

List of Appendices

SECTION 1 • EXECUTIVE SUMMARY

A Hunter Harvest Study (HHS) conducted from 2007 to 2015 was relaunched in 2019 and continued into 2020. The study included more than 60 participants of which 43 reported harvesting Caribou. Given an estimated 300 to 350 active hunters in the Hamlet of Baker Lake, the HHS represents from 12 to 14% of hunters in the community. With a total reported Caribou harvest of 652 in 2020, the total Caribou harvest in Baker Lake is estimated to range from 4,657 to 5,433 Caribou. This estimate is likely high because the current study attracted some of the more successful hunters (e.g., Baker Lake Hunters and Trappers Organization members) in the community.

Compared to other years, Caribou were harvested at a lower percentage within 5 km of the All-Weather Access Road and within the Regional Study Area. As such, harvest levels in 2020 in close proximity to mining facilities were well within threshold levels.

Lake Trout and Arctic Char were the most common species caught by fisherman. Unlike 2019, very few Lake Whitefish were caught, which may be due either to a decline in fishing effort in winter (e.g., nets set under the ice) and/or lower abundance of this species.

SECTION 2 • OVERVIEW

As outlined in the original TEMP (Cumberland 2006) and the June 2019 version (Agnico Eagle 2019), and as a requirement of NIRB Project Certificate No. 004 Terms and Conditions 51 and 54, the Baker Lake Hunter Harvest Study (HHS) was initiated in March 2007 by Agnico Eagle. The HHS was conducted in association with the Baker Lake Hunters and Trappers Association (HTO) to monitor and document the spatial distribution, seasonal patterns, and harvest rates of hunter kills and angler catches within the Meadowbank Regional Study Area (RSA).

After low participation during the first year of the study, methods were strategically adapted, participation increased steadily, and valuable information on harvest patterns in the Baker Lake area was collected. The HHS, through regular visits, contributed to developing a strong relationship with local harvesters, the HTO, and the Government of Nunavut, Department of Environment (GN). Data were provided annually in monitoring reports from 2007 to 2015 and in 2019.

The HHS was suspended for three years (2016 and 2018) to develop new approaches and direction. Following consultation with the HTO, Kivalliq Inuit Association (KivIA), GN, and other agencies in November 2016 (Winnipeg) and June 2017 (Ottawa), Agnico Eagle reinitiated the HHS in March 2019. The study approach was similar to previous years but suggestions and guidance received during the consultation period were incorporated into the study. The study was conducted through 2020 and continues into 2021.

SECTION 3 • OBJECTIVES

The primary objectives of the HHS are to monitor potential project-related effects on harvesting of wildlife by residents of Baker Lake. This objective is achieved by estimating the following key metrics:

1. The distribution of Caribou, Muskox, and Wolverine harvest by residents of Baker Lake; and
2. The total level (or an index of) Caribou, Muskox, and Wolverine harvest by residents of Baker Lake.

Other objectives of the HHS established in consultation with the Terrestrial Advisory Group (TAG) or other participants include:

1) Supporting creel surveys by gathering information on Arctic Char (*Salvelinus alpinus*), Lake Trout (*Salvelinus namaycush*), Lake Whitefish (*Coregonus clupeaformis*), and Arctic Grayling (*Thymallus arcticus*) catch rates and Inuit-use patterns in the Baker Lake area;

2) Understanding regional distribution of hunting and fishing activity;

3) Investigating seasonal timing of hunting and fishing activity; and

4) Determining whether increased harvest and catch rates are associated with the Meadowbank All-Weather Access Road (AWAR) and Whale Tail Hail Road (WTHR).

As discussed during consultation with stakeholders, the HHS will further seek to: a) increase and maintain the hunter participant rate in the future of the program; b) improve resource protection; c) improve hunter awareness and education; d) increase the integration of Inuit Qaujimajatuqangit and Traditional Knowledge; e) increase availability of data to support a collective approach to understanding wildlife harvest; and f) assist Agnico Eagle in mitigative actions and the GN in management decisions.

SECTION 4 • METHODOLOGY

The wildlife species that are the focus of the HHS are Caribou, Muskox and Wolverine; however, harvest data on other species, such as Wolf, Arctic Fox, geese and other birds is also collected. The few species in the study were deliberately chosen to make data entry and collection as simple as possible. To support creel surveys, data on fish harvest (Arctic Char, Lake Trout, Lake Whitefish, and Arctic Grayling) are also collected.

Inuit and non-Inuit residents, at least 16 years of age, are eligible to participate in the harvest survey. Harvest calendars are provided on a household basis rather than an individual basis in order to simplify data entry and collection, and reflect household hunting patterns. The harvest calendar is attractive and consists of local photographs of wildlife and Baker Lake residents (see **Appendix A** for 2020 calendar). Space is provided for each calendar day where harvest details can be documented. A map is provided at the end of the calendar that delineates a 4 km^2 UTM grid within the Baker Lake and Meadowbank areas. Each grid has a unique code to facilitate recording of information. When calendars are issued, participants or participating households are encouraged to write harvest details (e.g., number of animals, sex, age and location (i.e., grid code) for the appropriate date on the calendar.

Participants were interviewed in person only two times during the year (i.e., October 2020 and February 2021) by the harvest study coordinator. The lower number of visits in 2020 reflects logistical issues associated with Covid-19 (e.g., a mandatory 14-day quarantine was required in Winnipeg prior to travelling to Baker Lake). During the February 2021 interviews, remaining data from 2020 were collected. The purpose of the interviews is to ensure all harvest data are recorded on the calendars and collect incidental information to compliment calendar data, including notable Caribou movements, aggregations, and unique observations. Between interview periods, participants were often contacted by phone or social media to encourage recording of harvest data.

Features of the 2020 Hunter Harvest Study included: 1) increasing the amount of time researchers spent in the community interacting with participants on each visit; 2) building long-term relationships between participants and researchers; 3) increasing engagement with participants on social media platforms such as Facebook and Instagram; and 4) increasing incentives for participating in the study (e.g., gas vouchers and prizes).

SECTION 5 • HISTORICAL RESULTS

The Baker Lake HTO member list (provided by Ms. Joan Scottie [HTO Board Member] in 2008) consisted of 683 local area hunters/trappers/fishermen (collectively termed 'hunter' for the remainder of this memo), a number that has likely changed since then. The 2008 member count was a highly conservative (i.e., high) estimate of the number of individuals that hunt, trap or fish in the community as the list typically includes entire families. If just the heads of each household are counted, there were 389 potential hunters within the Baker Lake community in 2008. Although this value is still likely conservative (given that many of these individuals do not actively hunt or fish), the number is more comparable to the comprehensive 5-year Nunavut Wildlife Harvest Study (NWMB 2005) in which 336 Baker Lake hunters were contacted and interviewed.

Between 1996 and 2001, 18% of Caribou harvests were estimated to be within 5 km of the AWAR (prior to construction) and 67% of harvests occurred within the RSA (NWMB 2005). In the first year of the HHS study (2007), prior to completion of the AWAR, 34% of harvests were reported within 5 km of the AWAR alignment and 79% were recoded within the RSA. The HHS data (2007 to 2015, and 2019) fluctuated between 34 and 43% of reported harvest within 5 km of the AWAR, and between 64 and 85% within the RSA.

In 2008, 296 Caribou were reported as being harvested by Baker Lake HHS study participants. Harvest numbers steadily increased to 685 in 2011, and then decreased to 269 in 2014, the lowest reported harvest in seven years. In 2019, total Caribou harvested was 647, which was close to the high number recorded in 2011. Assuming that an average of approximately 10% of all Baker Lake hunters actively participated in the study (5% estimated for 2014), extrapolation of historical HHS values suggests approximately 3,000 to 6,000 Caribou are harvested each year in the Hamlet of Baker Lake. These estimates are in general agreement with historical harvest studies. Specifically, using the upper limit of the standard error in the Nunavut Wildlife Harvest Study, between 2,230 and 3,116 Caribou were harvested each year between 1996 and 2001 (NWMB 2005). Similarly, the Interdisciplinary Systems (IDS) report (IDS 1978) estimated an annual Caribou harvest in Baker Lake of 4,100 during the 1970s.

Based on the NWMB (2005) and HHS results (2007 to 2015, and 2019), highest Caribou harvests have occurred in September and October, with a second smaller peak in March and April. The similar pattern between the studies indicates that seasonal hunting preferences have not changed markedly in the last decade.

Reported harvests of Muskox and Wolverine remained low, precluding any interpretation of potential mine-related effects. Low densities of these species and their general aversion to humans require hunters to hunt well away from the AWAR; therefore, the presence of the AWAR is thought to have little effect on participant hunting patterns for Muskox and Wolverine. Wolverine harvest reports decreased from a maximum of 15 animals in 2010 to one (1) animal in 2015; however, in 2019, reported Wolverine harvests were at an all-time high of 18 individuals.

SECTION 6 • 2020 HUNTER HARVEST STUDY RESULTS

6.1 NUMBER OF HUNTERS

The HHS included 64 participants by the end of 2020. Of these, Caribou harvest data had been collected from 43 participants, which is considerably higher than the 28 participants that reported Caribou harvests in 2015, and slightly higher than the 42 hunters reporting harvests in 2019.

Based on the previous discussion of total numbers of hunters in the Hamlet of Baker Lake (**Section 5 Historical Results**), there were 389 potential hunters within the Baker Lake community in 2008. The number is comparable to the comprehensive 5-year Nunavut Wildlife Harvest Study (NWMB 2005) in which 336 Baker Lake hunters were contacted and interviewed. Discussions with Baker Lake HTO members in 2019 suggest the total number of hunters is over 300. Given the historical and current number of hunters in Baker Lake, an estimate of 300 to 350 active hunters is used in this analysis. Based on these numbers, the 43 hunters reporting Caribou harvest in 2020 conservatively represent from 12 to 14 % of total hunters in the community.

6.2 DISTRIBUTION OF HUNTING

Figure 6.1 shows the distribution of Caribou harvest within the HHS data collection area. Hunting is concentrated along the northern and southwestern ends of Baker Lake and along the AWAR to approximately KM 85. Limited harvests were reported along the Thelon River system in the vicinity of Schultz and Aberdeen lakes, and along the Kazan River near its mouth on Baker Lake. Annual variation in harvest location and intensity is attributable to numerous factors. For instance, many hunters have stated during informal discussions that they have a ‘favorite’ hunting area that they frequent each year. Some hunters have stated that they prefer hunting in ‘convenient’ locations, whereas other hunters prefer remote locations well away from frequented areas. A percentage of hunters also enjoyed partaking in long distance hunting trips over multiple days.

Between 1996 and 2001, 18% of Caribou harvests were estimated to be within 5 km of the AWAR (prior to construction) and 67% of harvests occurred within the RSA (NWMB 2005). In the first year of the HHS study (2007), prior to completion of the AWAR, 34% of harvests were reported within 5 km of the AWAR alignment and 79% were recorded within the RSA (see **Table 6.1**). The HHS data (2007 to 2015 and in 2019) fluctuated between 34 and 54% of reported harvest within 5 km of the AWAR, and between 64 and 85% within the RSA. The 2020 HHS data indicated that 30% of reported harvest occurred within 5 km of the AWAR, and 62% occurred within the RSA, representing the lowest proportion of Caribou harvested within 5 km of the AWAR since the road was built (see **Table 6.1**). One of the reasons for this may have been because of the large number of Caribou harvested in the vicinity of Baker Lake in fall 2020 (see **Figure 6.1**). As was the case in other years, threshold levels of 20% set for monitoring the effects of the Meadowbank mine development on the distribution of Caribou harvest were not exceeded (see **Figure 6.2**).

Average (2007 to 2020)	29 (78%)	6.2	38	23	76

6.3 MAGNITUDE OF HUNTING

In 2020, a total of 652 Caribou were reported as being harvested by 43 participants (see **Table 6.2**). Given that the 43 hunters represent an estimated 12 to 14% of the Baker Lake hunting community, and assuming that the average number of Caribou shot per hunter is similar, the total estimated number of Caribou harvested in 2020 ranges from 4,657 to 5,433 animals, which is almost identical to estimates for 2019. This estimate is considered to be conservative (i.e., high) since the Baker Lake Hunter Harvest Study targeted known hunters in the community with some known to be particularly successful.

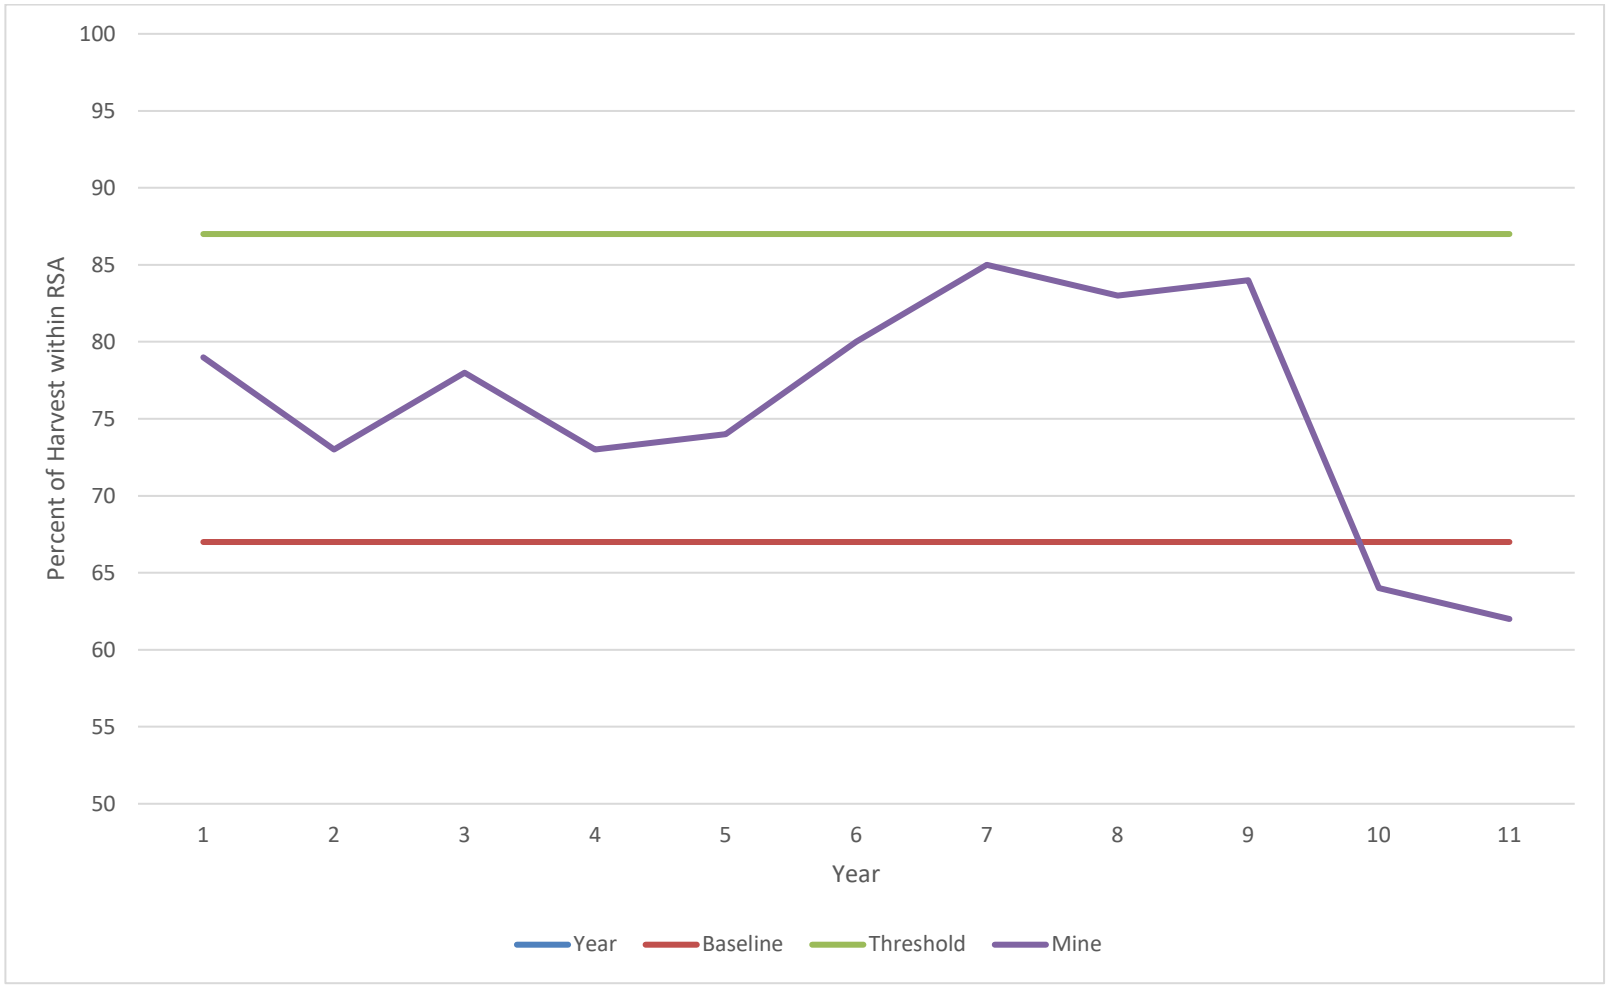

Figure 6.2: Percent of Caribou Harvest within the RSA from 2007 to 2015 (Years 1 to 9), and 2019 to 2020 (Years 10 and 11) Compared to Baseline and Threshold Levels.

6.4 SEASONAL DISTRIBUTION AND TIMING OF HUNTING

Based on the NWMB (2005) and HHS results (2007 to 2015; 2019 to 2020), highest Caribou harvests have occurred in September and October, with a second smaller peak in March and April (see **Figure 6.3**). The similar pattern between the studies indicates that seasonal hunting preferences have not changed markedly in the last decade. More details on the seasonal timing of harvest in 2020 can be found in **Figure 6.4** (i.e., numbers of animals harvested, numbers of participants, and average number of animals harvested by participant by month) and **Figure 6.5** (i.e., Caribou harvest numbers by season and proximity to the access roads).

The seasonal distribution of hunting is illustrated in **Figure 6.1,** which includes all 2020 results, and **Figures 6.6a** to **6.6d**, representing the spring, summer, fall and winter Caribou seasons outlined in the TEMP. In spring, overall Caribou hunting was low with hunting occurring north of Baker Lake and along the Thelon River system (**Figure 6.6a**). During the summer, Caribou were harvested across a larger area but particularly along the AWAR, just northeast of the Hamlet of Baker Lake, and in areas along Baker Lake accessible by boat (**Figure 6.6b**). In the fall, hunting was much more concentrated along the AWAR and in the Baker Lake area (**Figure 6.6c**). The large numbers harvested just northeast of Baker Lake in the fall reflects the large herd of Caribou that moved through the area in the fall. Some hunting in the fall also occurred along the Kazan River near Baker Lake. In winter, very few Caribou were hunted along the AWAR (**Figure 6.6d**). Successful hunters were those that travelled further afield by snowmobile (e.g., southwest end of Baker Lake, and between Schulz and Aberdeen lakes).

6.5 OTHER WILDLIFE SPECIES

There were no reported harvests for Muskox in 2020, precluding any interpretation of potential mine-related effects. Wolverines (total of 22 in 2020 – the highest yearly tally to date) were hunted close to Baker Lake, north of Aberdeen Lake and in other remote areas (see **Figure 6.7**). Wolves (total of 88 in 2020) were either trapped close to Baker Lake or hunted in larger numbers north of Aberdeen Lake in winter (**Figure 6.7**). Relatively low densities of Wolves and their general aversion to humans requires hunters to hunt well away from the AWAR. The presence of the AWAR is thought to have little effect on participant hunting patterns for Muskox, Wolverine and Wolf.

Arctic Fox (total of 11 in 2020) was primarily trapped in the vicinity of Baker Lake and east of Whitehills Lake, while Red Fox were harvested near Baker Lake and south of Tehek Lake (**Figure 6.8**). Two Grizzly Bear were taken near Pitz Lake, while one was taken in the southeastern end of the study area (**Figure 6.8**). Birds (e.g., goose, duck, ptarmigan etc.) and their eggs were reported as being collected around Baker Lake and north of Princess Mary Lake (**Figure 6.9).**

SECTION 7 • CREEL SURVEY RESULTS

7.1 NUMBER OF FISHERMAN

The number of fisherman reporting successful fishing trips in 2020 was 21, which is lower than the average of 23 fisherman from 2007 to 2015 and in 2019 (10 years), and lower than the 26 fisherman reporting success in 2019. The highest numbers of fisherman reporting success in 2020 were in the May to August period (see **Table 7.1**) (see **Section 7.4 Magnitude of Fishing**).

Table 7.1: Number of Fisherman in the Baker Lake Who have Recorded Fishing Success by Year and Month.

Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
2007			4	6	7	1	1		1			
2008	1	1	2	6	6	6	4	3			2	1

7.2 COMPOSITION OF CATCH

Three fish species were reported as being caught in 2020: Arctic Char, Lake Trout and Lake Whitefish. The most common fish species captured, Lake Trout, represented 67% of the total catch in 2020, which was higher than the average of 55% from 2007 to 2015 and in 2019 (see **Table 7.2**). In 2019 interviews, some fisherman indicated that Lake Whitefish numbers in Baker Lake were particularly high in 2019. Lower numbers of Lake Whitefish caught in 2020 could be due to lower abundance and/or reduced fishing effort.

Table 7.2: Total Number of Fish Caught between 2007 and 2015, and 2019 to 2020.

Species	2020	2019	2015	2014	2013	2012	2011	2010	2009	2008	2007	Total
Arctic Char	75	89	41	22	96	24	113	103	117	24	3	632
Arctic Grayling			29			1	1	3	1			35
Lake Trout	219	900	370	353	490	1,014	1,710	860	525	825	210	7,257
Lake Whitefish	32	1573	1386	651	50	471	460	326	51	192		5,160
Unidentified Fish	2	119										119
Totals	**328**	**2,681**	**1,826**	**1,026**	**636**	**1,510**	**2,284**	**1,292**	**694**	**1,041**	**213**	**13,203**

7.3 DISTRIBUTION OF FISHING

Fishing trips, regardless of success rate, did not generally occur beyond the immediate areas of Baker Lake, Whitehills Lake, and along the AWAR (see **Figure 7.1**). Some fishing occurred along the Thelon River system and associated lakes (**Figure 7.1)** during the summer when these areas can be accessed by boat. Results indicate that study participants are less willing to travel long distances to catch fish, regardless of AWAR access, likely due to the abundance of fish in close proximity to the Hamlet of Baker Lake.

7.4 MAGNITUDE OF FISHING

Unlike in 2019, the average number of fish harvested per fisherman was highest in the summer months (**Figure 7.2**). In 2019, the high winter numbers reflected the high catches of Lake Whitefish and Lake Trout caught in nets set under the ice. In 2020, the most commonly captured fish species, in order of abundance, were Lake Trout, Arctic Char, and Lake Whitefish (see **Table 7.3**). Few Lake Whitefish were reported as being caught in 2020 compared to 2019, which is either due to lower abundance and/or reduced effort.

7.5 SEASONAL TIMING OF FISHING

In 2020, fishing periods with the most active fisherman was from May to August (see **Table 7.2**). The periods with the most fish caught included the summer months (especially June and July), which reflects the high number of Lake Trout caught by fisherman heading out on the land after ice melt (**Figure 7.3**).This trend can be observed in the overall trendsfrom 2007 to 2015 and 2019 (**Figure 7.3)**; however, the winter peaks of fishing observed in 2019 were not seen in 2020.

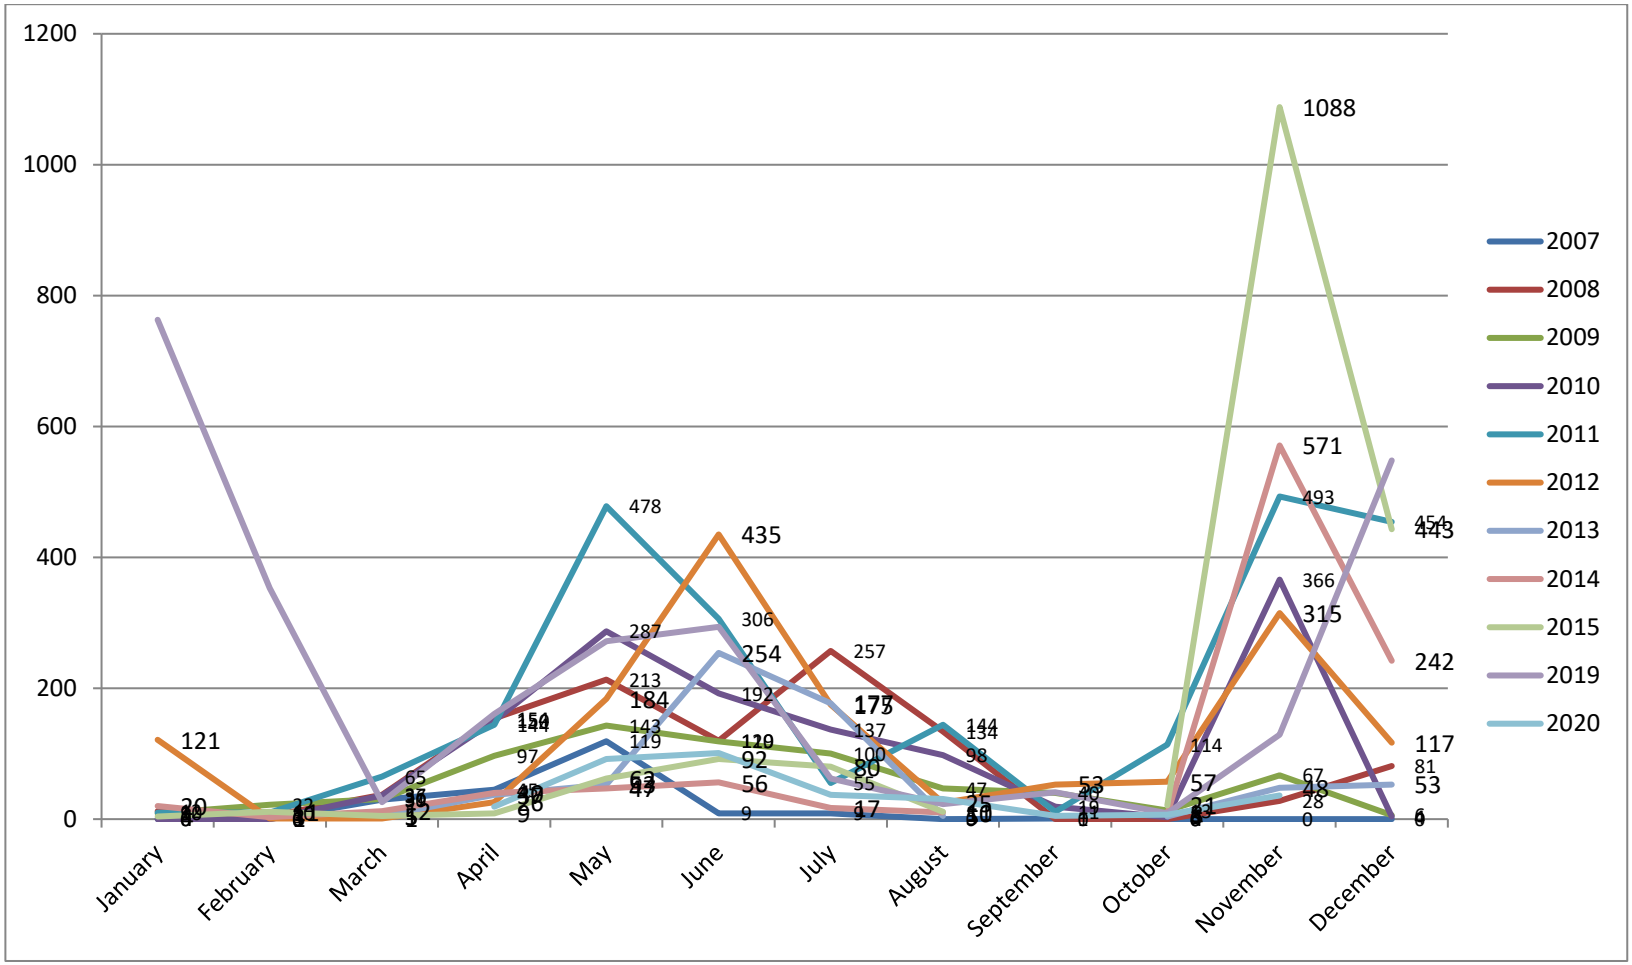

Figure 7.3: Seasonal Trends in Fishing in the Baker Lake Area from 2007 to 2015, and 2019 to 2020.

SECTION 8 • ACCURACY OF IMPACT PREDICTIONS

Table 8.1 provides a summary of the impact predictions identified in the original TEMP (Cumberland 2006) and the updated June 2019 version (Agnico Eagle 2019). The 2020 HHS data were compared to the impact prediction thresholds to evaluate adherence to the impact predictions and the provision of adaptive management, as either a necessary or proactive measure. No thresholds were surpassed in 2020.

Table 8.1: Accuracy of Impact Predictions – Baker Lake Hunter Harvest Study

Potential Effect	Threshold	Threshold Exceeded (2020)	Adaptive Management Implemented	Status
Meadowbank All-Weather Access Road				
Hunting by Baker Lake Residents	The AWAR will not result in significant changes in the spatial distribution, seasonal pattern, or harvest levels of Caribou kills by Baker Lake hunters. Changes will not exceed 20% of historical harvest activities within the RSA	NO (62% of harvest in RSA in 2020 compared to 67% baseline; average of 76% of harvest within RSA since 2007)	Future discussion with HTO and GN representatives required to identify management options	Hunter Harvest Study Creel Survey
Whale Tail Haul Road				
Hunting by Baker Lake Residents	No change in harvest	NO (No harvests recorded within 8 km of the Whale Tail Haul Road)	None required. Access by hunters is restricted in the growing season and very limited hunting occurs in the winter.	Hunter Harvest Study Satellite-collaring Program

SECTION 9 • MANAGEMENT RECOMMENDATIONS

The Hunter Harvest Study and Creel Survey should be continued on an annual basis to monitor the hunting and fishing patterns of Baker Lake residents, and the potential effects of the mine. Meetings with participants every four months (3 times/year) in 2021 are particularly important in maintaining contact, building relationships, expanding the study and collecting good harvest data. The total number of planned visits per year was reduced to three from four because of the added logistical constraints associated with mandatory quarantine prior to travel to Nunavut. Despite the decrease in visits, participation rates can be maintained by continuing to use social media platforms such as Facebook and Instagram, expanding connections on these platforms, ensuring that all participants are visited during the three scheduled field visits, and continuing with distribution of the well-received gas vouchers and year-end prizes while in the community.

How to Use the Baker Lake Harvest Calendar

Agnico Eagle Mines Ltd., in cooperation with the Baker Lake Hunters and Trappers Organization (HTO), want to understand hunting and fishing patterns by Baker Lake residents. Specifically, we want to understand how the Meadowbank and Whale Tail Gold Project, located north of Baker Lake, might change traditional harvesting patterns. To ensure that traditional hunting and fishing activities are not negatively affected, we have developed this calendar where participants can record harvest information throughout the year.

Near the back of the calendar is a page that shows the animal and fish species that are included in the study. Please write down the species, number, sex, and location of animals or fish that you have harvested on each date on the calendar. When writing down the location, please use the XY coordinate system provided on the nine maps at the back of the calendar.

For example, if you harvested a male caribou on January 16th on Big Hips Island you would write down "1 male caribou, AF19" in the January 16th square of the calendar.

You will also be visited or contacted by the hunter harvest coordinator occasionally throughout the year. The coordinator's job will be much easier if you write down your harvest information in the calendar as soon as possible.

Please return the calendar to the Agnico Eagle office in Baker Lake at the end of the year or give the calendar to the coordinator when he visits in January. Although each participant will receive a gift expressing our thanks, a draw will also be held in January for a number of high quality prizes.

Please contact the Baker Lake Harvest Study Coordinator, Martin Gebauer at (604) 720-6396 (martin@gebauerassociates.com) if you have any questions. Contacts at Agnico Eagle Mines include the Environmental Coordinator at (819) 759-3555, ext. 4606744.
