## EXECUTIVE SUMMARY

---

Agnico Eagle Mines Limited – Meadowbank Division (Agnico Eagle) is developing the Whale Tail Pit and Haul Road Project (Project), a satellite deposit located on the Amaruq property, to extend mine operations and milling at Meadowbank Mine. In 2020 the Whale Tail Expansion Project (Expansion Project) was approved, permitting Agnico Eagle to expand and extend the Whale Tail Pit operations to include a larger Whale Tail open pit, development of the IVR open pit, and underground operations while continuing to operate and process ore at the Meadowbank Mine.

The Amaruq property is a 408 square kilometre (km<sup>2</sup>) site located on Inuit Owned Land (IOL) approximately 150 kilometres (km) north of the hamlet of Baker Lake and approximately 50 km northwest of Meadowbank Mine in the Kivalliq Region of Nunavut. The deposit will be mined as two open pits (i.e., Whale Tail Pit and IVR Pit) and underground operations, and ore will be hauled to the approved infrastructure at Meadowbank Mine for milling.

The open pit mine, mined by truck-and-shovel operation, includes four development phases: 1 year of construction (complete), 7 years of mine operations, 25 years of closure, and the post closure period. On September 30<sup>th</sup>, 2019 commercial production began at the Whale Tail Pit. The Expansion Project includes mining an additional 15.2 million tonnes of ore from the expanded Whale Tail Pit, the IVR open pit and underground operations. This expanded resource will be extracted over an approximately three-year period. In total, the ore milling period for the Whale Tail project has been expanded and extended over approximately an eight-year period from 2019 to 2026.

The water management objectives are to minimize potential impacts to the quantity and quality of surface water at the mine site. Water management structures (water retention dikes/berms and diversion channels) have been and will be constructed, dependent on the potential presence and volume of water, to contain and manage the contact water from the areas affected by the mine or mining activities. The major water management infrastructure includes: contact water collection ponds, freshwater collection ponds, diversion channels, water retention dikes, dams, culverts, seepage collection systems, water treatment plants for effluent, a potable water treatment plant, a sewage treatment plant, and discharge diffusers. Non-contact water is managed in specific ponds with their own pumping systems.

This Water Management Plan for the Project describes the main objectives pertaining to water management, which are to limit and/or stop the flow of surface water runoff in the pit and to limit the impact on the local environment. In developing the water management plan, the following principles were followed:

- keep the different water types separated as much as possible;
- control and minimize contact water through diversion and containment;

- minimize freshwater consumption by recycling and reusing the contact and process water wherever feasible; and
- meet discharge criteria before any site contact water is released to the downstream environment.

During mine construction and operations, contact water originating from affected areas on surface is intercepted, diverted and collected within the various collection ponds. The collected water on the mine site is pumped and stored in the Whale Tail Attenuation Pond starting in the summer of 2020, where the contact water is treated by the Water Treatment Plant (WTP) (as required according to water quality) prior to discharge to the receiving environment or reused in the operations. Prior to the summer of 2020 Whale Tail North Pond was used for non-contact water management and Quarry 1 was used for contact water management.

During operations, site contact water quality is predicted to exceed established effluent criteria (i.e. under the Whale Tail Water Licence (2AM-WTP1830) for arsenic and total dissolved solids in the Whale Tail Waste Rock Storage Facility (WRSF) Pond and in the Whale Tail Pit sump. Therefore, this water is controlled by Whale Tail WRSF Dike and the Whale Tail WRSF Pond. The Whale Tail WRSF Pond water will report with all other contact water and will be mixed in the Whale Tail and IVR Attenuation Ponds and treated during operations.

During operations when the mine is at its maximum footprint, the conservative predictions of future water quality indicate that most parameter concentrations in the downstream environment are below CEQG-AL except for arsenic. A site wide water balance and water quality modeling will be updated yearly, and end pit water quality modelling will be conducted as needed to update predictions.

Water management during closure and reclamation will involve actively filling the underground facilities and IVR Pit, and passively allowing the Whale Tail Attenuation Pond and the Whale Tail Pit to flood. The Groundwater Storage Ponds, and IVR Attenuation Pond will be emptied at the start of closure and backfilled with NPAG/non-ML waste rock. The Whale Tail and IVR WRSFs will be progressively covered with NPAG/non-ML waste rock throughout operations and are expected to be completely covered at the beginning of closure. Contact water management systems will remain on site until monitoring results demonstrate that water quality is acceptable for discharge of all contact water to the environment without further treatment. Once water quality meets the discharge criteria, the water management systems will be decommissioned to allow the water to naturally flow to the receiving environment. Through best management practices and mitigation, the predicted water quality of Whale Tail Lake (North Basin) meets aquatic life guidelines post-closure.

The updated water quality model shows a stable trend in the water quality indicators through operations. At closure and post-closure, flooded pit water quality is predicted to meet receiving water quality criteria when flooding is complete, allowing reconnection with the downstream receiving environment. Arsenic release from the submerged Whale Tail Pit walls is anticipated once pit-flooding commences but is expected to be a relatively short-lived source to the flooded pit lake. The site wide

water balance is updated on a regular basis and end pit water quality modelling will be conducted as needed to update predictions.

Dikes will not be breached until the water quality in the flooded area meets the approved water quality objectives. During mine closure, no mine discharges will occur to the downstream receiving environment since all contact waters are diverted to the open pit, underground and Whale Tail Lake (North Basin) for re-flooding. The water quality in the open pit and Whale Tail Lake (North Basin) averaged over the closure period is predicted to be similar to that of the last year of operations, with similar maximum and average concentrations.

**SECTION 1 • INTRODUCTION**

---

Agnico Eagle Mines Limited – Meadowbank Division (Agnico Eagle) is developing the Whale Tail Pit and Haul Road Project (Project), a satellite deposit located on the Amaruq property, to continue mine operations and milling at Meadowbank Mine. In 2020 the Whale Tail Expansion Project (Expansion Project) was approved, allowing Agnico Eagle to expand and extend the Whale Tail Pit operations to include a larger Whale Tail open pit, development of the IVR open pit, and underground operations while continuing to operate and process ore at the Meadowbank Mine.

The Amaruq property is a 408 square kilometre (km<sup>2</sup>) site located on Inuit Owned Land approximately 150 kilometres (km) north of the hamlet of Baker Lake and approximately 50 km northwest of Meadowbank Mine in the Kivalliq Region of Nunavut. The deposit will be mined as two open pits (i.e., Whale Tail Pit and IVR Pit) and underground operations, and ore will be hauled to the approved infrastructure at Meadowbank Mine for milling.

The open pit and underground mine, mined by truck-and-shovel operation, includes four development phases: 1 year of construction (complete), 7 years of mine operations, 16 years of closure, and the post closure period. In total, the ore milling period for the Whale Tail project has been expanded and extended over approximately an eight-year period from 2019 to 2026.

The construction and preparation of material started in summer 2018 after all permits and authorizations were received and construction of the dikes started in the third quarter of Year -1 (2018). Focus on site preparation and construction of infrastructure, with the development of the open-pit to produce construction material continued in 2018 and 2019. On September 30<sup>th</sup>, 2019 commercial production began.

Waste rock and overburden will be stored in the Waste Rock Storage Facility (Whale Tail WRSF and IVR WRSF) and ore stockpiled on the ore pads. The waste rock storage footprint, water management infrastructure and camp have been designed and considers up to eight years to allow for expected resource growth. The underground WRSF (AP-5 location) that was permitted under the Type B will be expanded and became a facility regulated under the Type A Water Licence (2AM-WTP1830). Agnico Eagle will increase the footprint of the underground area to the north to accommodate additional waste storage. The existing tailings facility at Meadowbank Mine will continue to be used for tailings disposal. All tailings treatment and disposal will remain consistent with the current Project Certificate (No. 004).

Closure will occur from Year 8 (2026) to Year 24 (2042) after the completion of milling and will include removal of the non-essential site infrastructure and flooding of the mined-out open pits and underground mine as well as reestablishment of the natural Lake A17 (Whale Tail Lake) level. Only essential infrastructure related to water treatment will remain on site during the closure and post-closure phases. Accordingly, in addition to the Water Treatment Plant (WTP), a part of the camp,

including all infrastructure allowing camp autonomy and security, as well as site roads, will be maintained following the operational phase (see more information in Whale Tail Pit Interim Closure and Reclamation Plan). Post-closure is expected from Year 24 (2042) onwards. Site and surrounding environment monitoring started from the beginning of the construction and will be completed during the post-closure phase when it is shown that the site and water quality meets the regulatory closure objectives.

Table 1.1 summarizes the overview of the timeline and general activities.

TSF = Tailings Storage Facility

This document presents the Water Management Plan (Plan) for the Project in accordance with Part B, conditions 14 and 15, and Part E, condition 5, of the Nunavut Water Board (NWB) Water License 2AM – WTP1830. It is also addressing Term and Condition n. 6 of the Nunavut Impact Review Board (NIRB) project certificate. Agnico Eagle has applied the same water management and water balance approach in this document as used for the annual Meadowbank Mine Water Management Report (Agnico Eagle, 2021). The purpose of this Plan is to provide consolidated information on water management, required water management infrastructure, and water balance for the operations of Whale Tail Pit and IVR Pit as satellite pits for the Meadowbank Mine. This plan also includes lessons learned on water management at site during the first year of the project. Finally, this plan includes the Whale Tail water quality forecast update (Appendix D).

This Plan will be updated as required to reflect any changes that occur in operations or economic feasibility, and to incorporate new information and the latest technology, where appropriate.

---

**SECTION 2 • BACKGROUND INFORMATION**

---

**2.1 Site Conditions**

The general mine site location for the Project is presented in Figure 2-1.

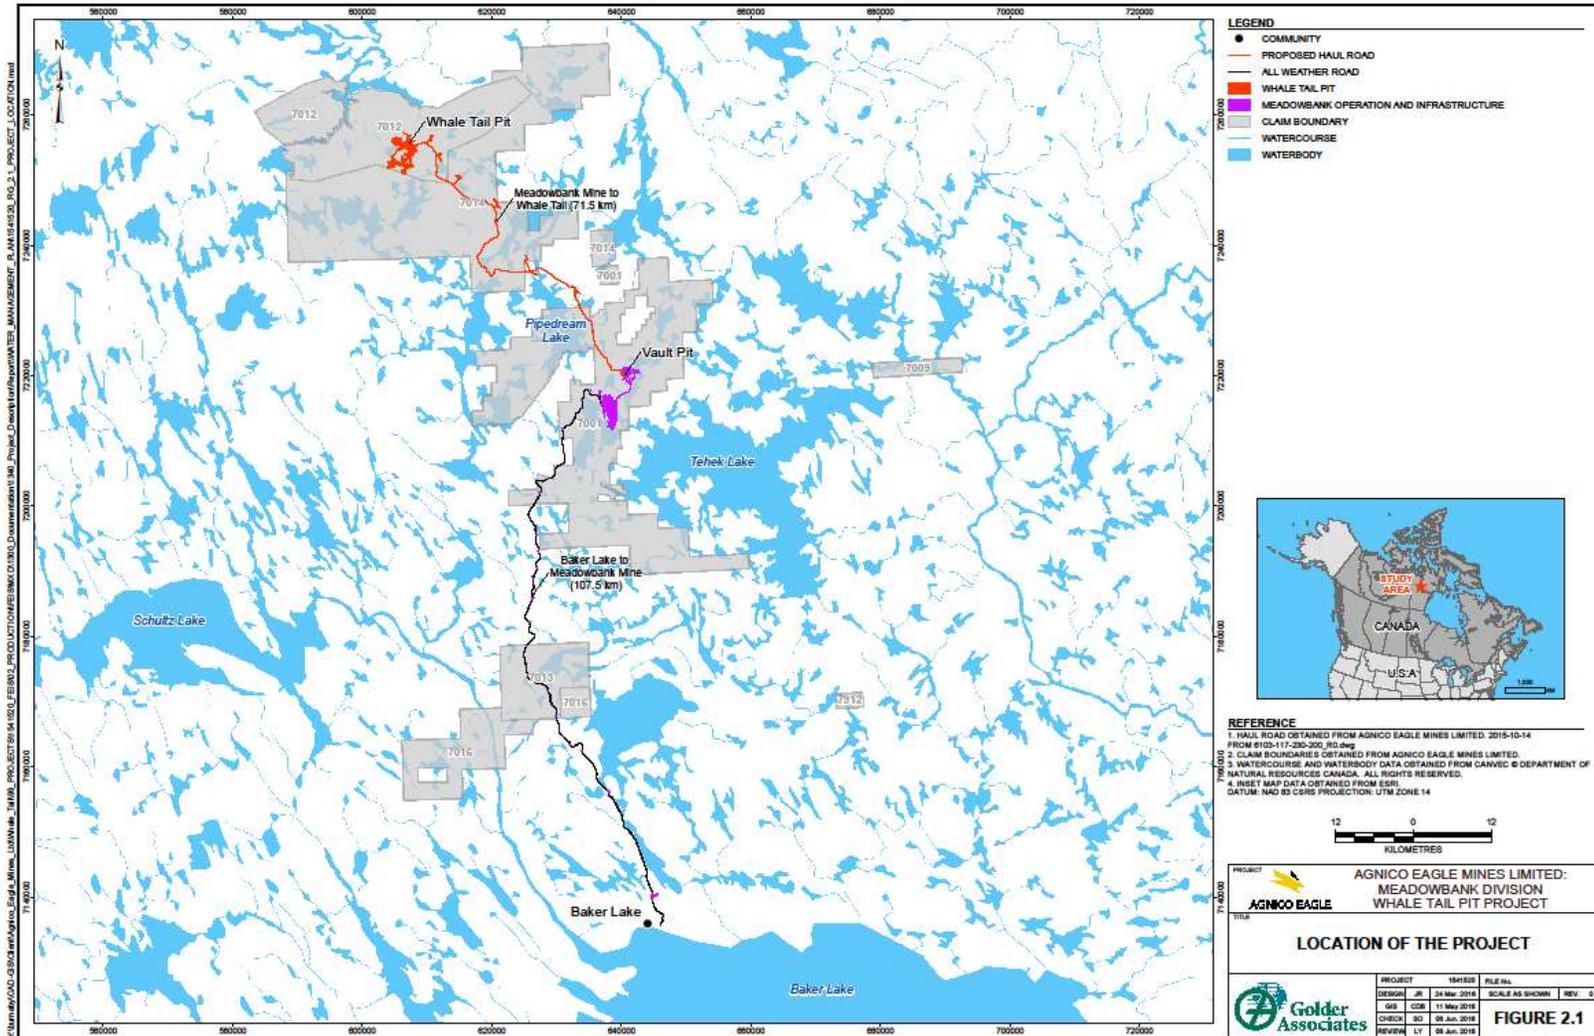

**2.1.1 Climate**

Climate characteristics presented herein were extracted from the permitting level engineering report (SNC 2015).

The Project is in an arid arctic environment that experiences extreme winter conditions, with an annual mean temperature of -11.3 degrees Celsius (°C). The monthly mean temperature ranges from -31.3°C in January to 11.6°C in June, with above-freezing mean temperatures from June to September. The annual mean total precipitation at the Project is 249 millimetres (mm), with 59 percent (%) of precipitation falling as rain, and 41% falling as snow. Mean annual losses were estimated to be 248 mm for lake evaporation, 80 mm for evapotranspiration, and 72 mm for sublimation. Mean annual temperature, precipitation, and losses characteristics are presented in Table 2.1.

Short-duration rainfall, representative of the Project are presented in Table 2.2, based on intensity-duration-frequency curves available from the Baker Lake A meteorological station (Station ID 300500) operated by the Government of Canada (2015).

## 2.1.2 Permafrost and Hydrogeology

### 2.1.2.1 Permafrost Conditions and Assessment

Thermal assessments have been completed that contribute to the understanding of the permafrost conditions near the Whale Tail Pit, IVR Pit and Underground. An update of the Whale Tail Thermal Assessment was conducted in April 2019 (Golder 2019b). The thermal assessment evaluated existing permafrost characteristics in the Whale Tail Lake and Project area and existing talik conditions under the Whale Tail Lake adjacent to the Project. The thermal assessment was completed based on available thermistor data to date, as well as the results of a thermal 2D modelling exercise and 3D block model prepared to assess permafrost conditions and the extent of talik formations beneath the Whale Tail Lake.

The updated thermal assessment of the project also took into consideration the groundwater monitoring program (Westbay sampling) that took place in November 2018 (Golder 2019b). The 2018 groundwater monitoring program indicates that water samples were collected from fixed ports along the Westbay system between 276 m and 499 m below the ground surface, which suggests that the Westbay system is installed in open talik, or water sampling would not have been possible at depth.

The mine site is located in an area of continuous permafrost, as shown on **Error! Reference source not found.** Based on measurements of ground temperatures (Knight Piésold 2015), the depth of permafrost at the mine site is estimated to be in the order of 425 metres (m) outside of the influence of waterbodies. The depth of the permafrost and active layer will vary based on proximity to the lakes, overburden thickness, vegetation, climate conditions, and slope direction. The typical depth of the active layer is 2 m in this region of Canada. The estimated depth of zero amplitude from the temperature profiles ranges from 18 m to 35 m. The temperatures at the depths of zero amplitude are in the range of -3.1 °C to -8.6 °C for on land thermistors and 2.7 °C for AMQ17-1265A. The geothermal gradient estimated based on the lowest 70 to 100 m of the thermistor strings is in the range of 0.004 °C/m (AMQ15-294) to 0.052 °C/m. Late-winter ice thickness on freshwater lakes is approximately 2.0 m. Ice covers usually appear by the end of October and are completely formed in early November. The spring ice melt typically begins in mid-June and is complete by early July.

The information presented in the following section is based on the updated report *Hydrogeological Assessment and Modelling Whale Tail Pit - Expansion Project* (Golder 2019e). The following summarizes the updated understanding of permafrost conditions in the Expansion Project Area:

- The depth of permafrost outside of the influence of lakes is estimated to be between 452 m and 522 m based on thermal gradients and ground temperatures at the lowest portions of the thermistor strings. The depth of permafrost increases with increasing distance from lakes with talik.
- Considering the 2D thermal modelling and 3D block model, the assessment indicated that:

- Under the northern portion of the lake below Whale Tail Pit, there is likely a closed talik formation (Section C of the thermal modelling report, reproduced on Figure 3 of this report).
- Open talik conditions are probable in the southern portion of the lake where the Whale Tail Lake becomes wider (Section G of the thermal modelling report, reproduced on Figure 4 of this report).
- Permafrost depth is between 480 m and 550 m for ground away from the Whale Tail Lake, and between 350 m and 450 m below surface in portions beneath the Whale Tail Lake where a closed talik is present.
- The cryopeg thickness is likely between 20 m to 30 m.

#### 2.1.2.2 Groundwater Flow Regime

Groundwater characteristics at the mine site are detailed in the Expansion Project Final Environmental Impact Statement (FEIS), Addendum Volume 6, Section 6.3. The hydrogeological model was updated in May 2019 with hydrogeological modelling completed for the Expansion Project since submission of the FEIS addendum in December 2018 (Golder 2019e). The model was updated based on results of monitoring at the Westbay system in November 2018, supplemental packer testing in December 2018, and additional 2D and 3D thermal analysis in 2019. The updated hydrogeological model was then used to provide revised predictions of groundwater inflow and total dissolved solids (TDS) concentrations during dewatering, mining, pit and underground flooding, and long-term post-closure (reflooded) conditions.

Two groundwater flow regimes occur at the Expansion Project: a deep groundwater flow regime beneath permafrost and a shallow groundwater flow system located in the active (seasonally thawed) layer near the ground surface. Except for areas of taliks beneath lakes, the two groundwater regimes are isolated from one another by thick permafrost.

Groundwater flow within the deep groundwater flow regime is limited to the sub-permafrost zone. This deep groundwater flow regime is connected to ground surface by open taliks underlying larger lakes. The elevations of these lakes are the primary control of groundwater flow directions in the deep groundwater flow regime, with density gradients providing a potential secondary control. The elevations of these lakes in the baseline study area indicate that Whale Tail Lake is likely a groundwater discharge zone at the south end of the Lake, with flow from Lake A60 to Whale Tail Lake, and a groundwater recharge zone at the north end of the Lake, with flow from Whale Tail Lake to Lake DS1 (Figure 2-3).

While portions of Whale Tail Pit is located within unfrozen rock, the IVR Pit and the Underground Project are fully contained within permafrost as per current planification. Groundwater inflow is therefore only expected during operations in the Whale Tail Pit.

Mining of the Whale Tail Pit occurs within the talik underlying Whale Tail Lake, whereas the latest version of the Underground Project is located in permafrost. The Underground is not directly connected to either Whale Tail Pit or IVR Pit.

During mining, the Whale Tail Pit will act as a sink for groundwater flow, with seepage faces developing along the portions of the pit walls. In response to the deepening of the mine workings, groundwater will be induced to flow through bedrock to the Whale Tail Pit. Mine inflow will originate primarily from Whale Tail Lake (South Basin), the Whale Tail Attenuation Pond, and deep bedrock underlying the permafrost.

Figure 2.2 Permafrost Map of Canada

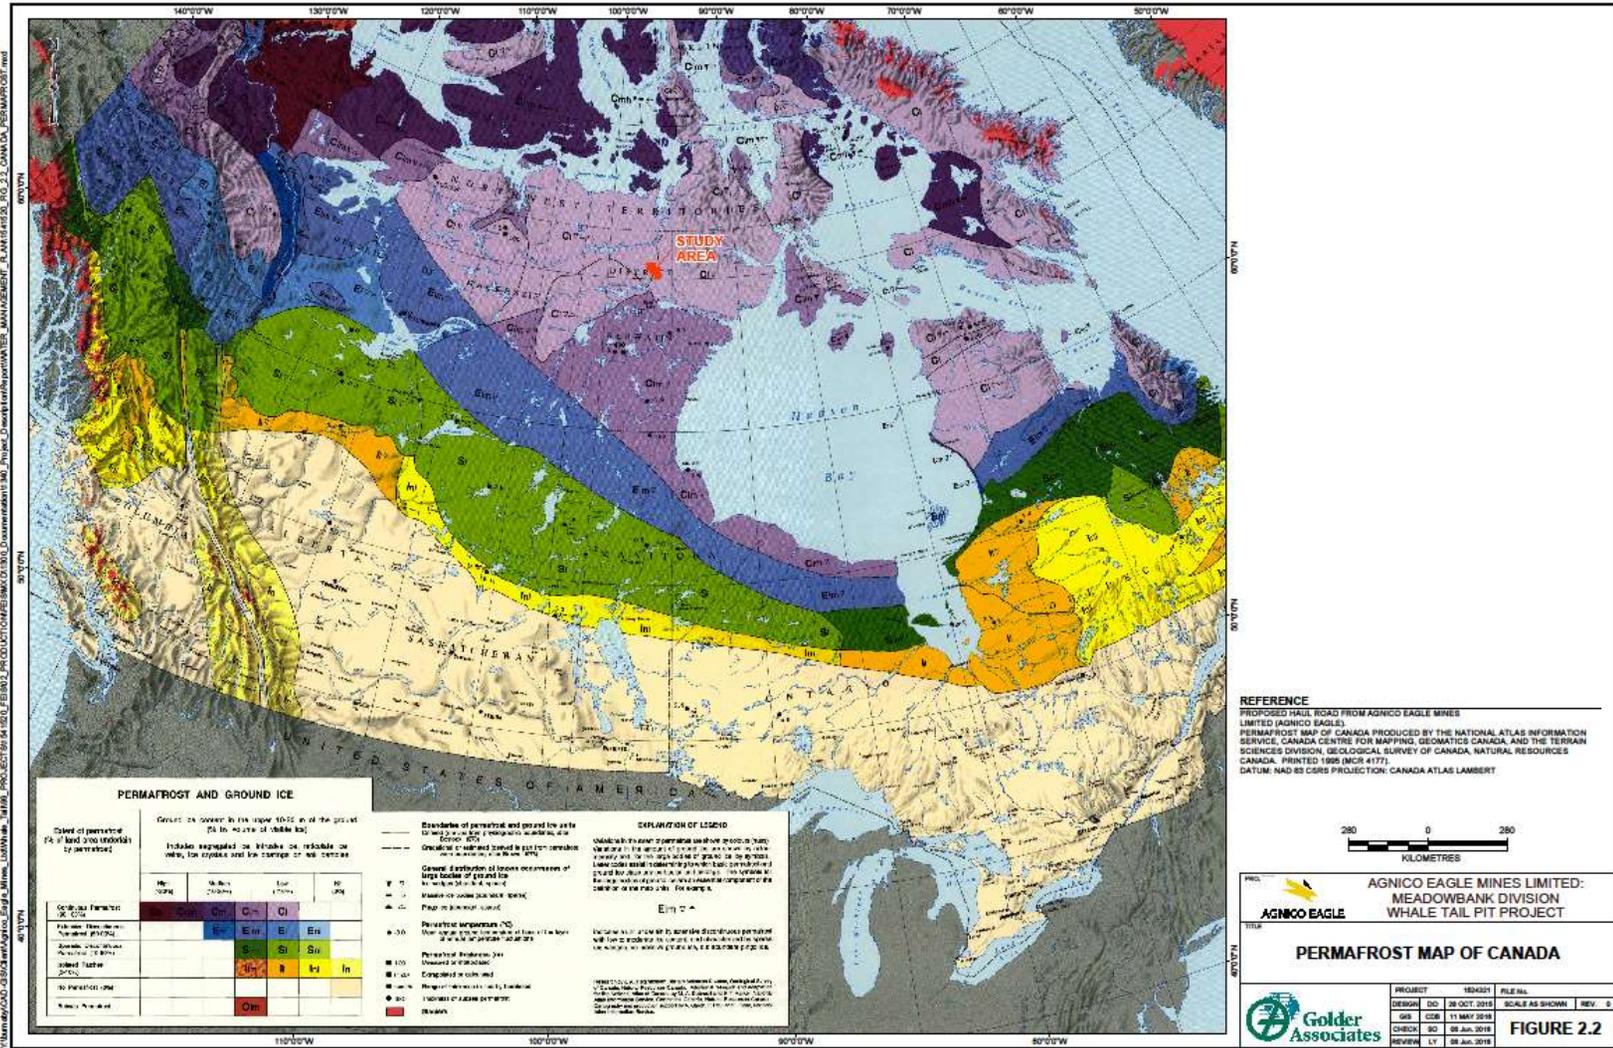

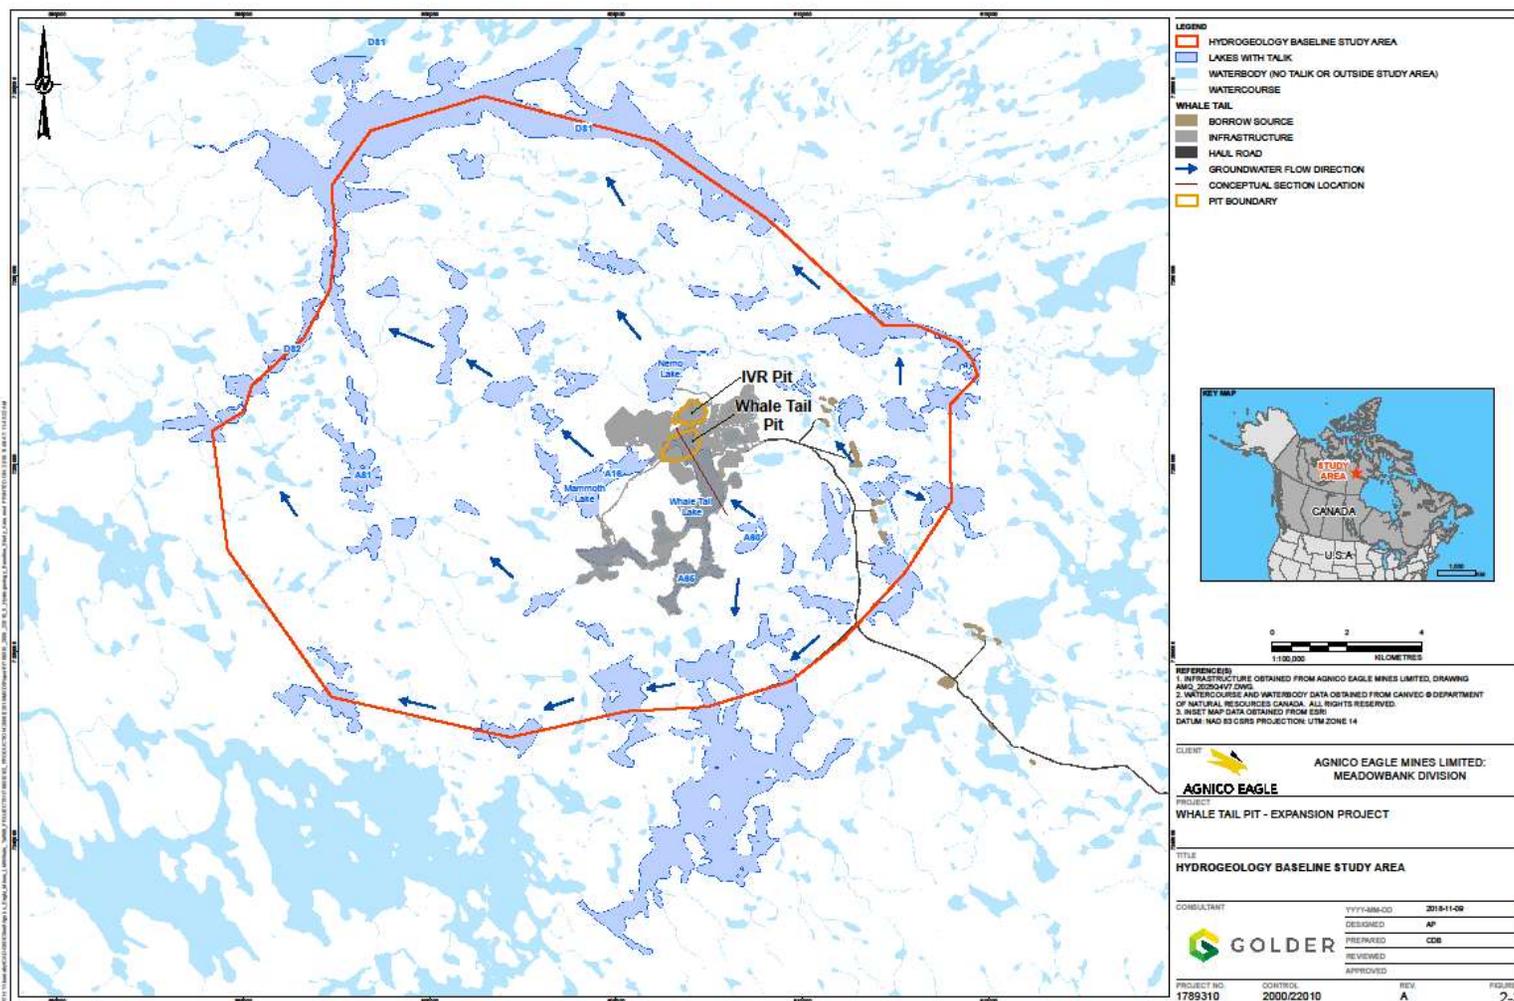

Figure 2.3 Hydrogeology Baseline Study Area

### 2.1.3 Hydrology

Hydrology characteristics were extracted from the surface water quantity impact assessment section (FEIS, Addendum Volume 6, Section 6.3; Volume 6, Appendix 6-C).

The mine site is located in the A watershed (i.e., where Lake A17 [Whale Tail Lake] and Lake A16 [Mammoth Lake] are located), and water management activities are planned in the A watershed and the C watershed (i.e., where Lake C38 [Nemo Lake] is located); these two watersheds drain into Lake DS1, which drains north to the Meadowbank River. These watersheds comprise an extensive network of lakes, ponds, and interconnecting streams, and have lake water surface fractions (i.e., the ratio of lake area to watershed area) of 16% (A watershed) and 23% (C watershed).

Shorelines in the mine site area exhibit a consistent terrain type related to shorelines that have developed in morainal material. These morainal shorelines were observed at all lakes visited during the 2015 field survey. Limited areas of bedrock and shallowly sloped sandy shorelines were also observed. As a general characteristic for the surveyed shorelines, the predominant materials are boulder gardens mixed with cobble with very limited soils or organic materials on top. The outlet channels are relatively short with a low sinuosity (i.e., close to 1.0) and exhibit the same characteristics for streambed materials, which results in interstitial flow through large boulders or below the surface likely close to the bedrock, making flow difficult to observe and measure.

Discharges of watercourses in the mine site area typically peak in late-May to mid-June from snowmelt, rapidly decline in July, and low discharges prevail until frozen conditions in October to November, with a secondary peak in September from rainfall events. Watercourses in the Project area are frozen over the winter.

Derived long-term mean annual water yield for selected lakes in the mine site area vary between 86 mm at Lake C38 (Nemo Lake) to 230 mm at Lake A69. These water yields are like regional water yields reported at the Meadowbank Mine.

### 2.1.4 Surface Water Quality

Water quality characteristics were extracted from the water quality baseline report (FEIS, Volume 6, Appendix 6-G, Agnico Eagle, 2016) and the water quality impact assessment section (FEIS, Volume 6, Section 6.4, Agnico Eagle, 2016). Baseline water quality sampling was conducted at lakes and tributaries in various watersheds in the study area during open-water conditions in 2014 and 2015.

Surface water collected from lakes during the open water season was characteristic of low productivity headwater lakes in the Arctic; soft water, with low alkalinity, low turbidity (and corresponding high Secchi depth) and low total suspended solids (TSS). There was minor thermal stratification evident at some deeper lake stations. The water columns of lakes are well oxygenated, and pH was neutral to slightly acidic. The majority of water chemistry parameter concentrations were below the analytical detection limit and below the Canadian Council of Ministers of the Environment

water quality guidelines for the protection of aquatic life (CCME, 1999) and the Canadian drinking water guidelines (Health Canada, 2014).

Samples collected from the tributaries showed them to be well oxygenated, with low conductivity, and neutral to slightly alkaline pH. As with the lakes, most of the water chemistry parameter concentrations were below the aquatic life and drinking water quality guidelines.

### **2.1.5 Climate Change**

Climate change information presented herein was extracted from the air quality impact assessment section (FEIS, Addendum Volume 4, Section 4.2).

The climate in the Arctic is changing faster than at mid-latitudes (IPCC, 2014). The most recent set of climate model projections (CMIP5) predict an Arctic-wide year 2100 multi-model mean temperature increase of +13°C in late fall and +5°C in late spring under the IPCC's "business as usual scenario" (RCP8.5). IPCC climate change mitigation scenario RCP4.5 results in a year 2100 multi-model Arctic wide prediction of +7°C in late fall and +3°C in late spring (Overland et al., 2013). The effects of changes of this magnitude to terrestrial, aquatic and marine ecosystems, social and economic systems of the Arctic are an active area of research. However, the short duration of the proposed Project means that climate change related effects to the Project are likely negligible.

### **2.1.6 Seismic Zone**

The mine site is in an area of relatively low seismic risk. The peak ground acceleration (PGA) for the area was estimated using seismic hazard calculator from the 2010 National Building Code of Canada website ([http://www.earthquakescanada.nrcan.gc.ca/hazard-alea/interpolat/index\\_2010-eng.php](http://www.earthquakescanada.nrcan.gc.ca/hazard-alea/interpolat/index_2010-eng.php)). The estimated PGA is 0.019 g for a 5% in 50-year probability of exceedance (0.001 per annum or 1 in 1,000-year return) and 0.036 g for a 2% in 50-year probability of exceedance (0.000404 per annum or 1 in 2,475 year return) for the area.

## **2.2 Mine Operations Description**

### **2.2.1 Mine Development Plan**

Whale Tail Open Pit, IVR Open Pit and Underground mining will be mined using the traditional open pit method and long hole mining (95%) with some mechanized cut and fill in flat areas. The mining is planned from 2019 to 2025, while milling will continue through 2026.

Two mine waste streams will be produced at Whale Tail Pit; waste rock and overburden. Ore will be stockpiled in a series of stockpiles located adjacent to the pits. As ore is transported to the Meadowbank Mine for processing, a third mine waste stream, tailings, will be produced at Meadowbank Mine (refer to the Whale Tail Pit – Waste Rock Management Plan, Agnico Eagle, 2021a). The operation, management, and monitoring of the TSF is regulated under the Agnico Eagle Type A water Licence 2AM-MEA1530.

The mine development will include the following major infrastructure:

- industrial area (camp, power plant, heli-pad, landfarm and garage)
- crusher
- ore stockpiles
- rock and overburden storage facilities
- landfill
- haul and access roads
- underground mine
- two open pits

In addition, the mine development will include construction of water management facilities, listed in Section 3.1.2.

**2.2.2 Summary of Mine Waste Management**

This section is a summary of the mine waste management plan. More detailed information on mine waste management is presented in the Whale Tail Pit – Waste Rock Management Plan, Agnico Eagle, 2021a. Water management associated with mine waste management is described in Section 3.1.4 of this document. Two areas of the site were identified as the Whale Tail WRSF and the IVR WRSF to store waste rock and overburden material, as shown in Appendix A. Table 2.3 presents a summary of the proposed usage or destination for the waste material.

**Table 2.3 Summary of Mine Waste Destination**

Mine Waste Stream	Waste Destination
Overburden	<ul style="list-style-type: none"> <li>• Temporary storage West of Whale Tail Lake</li> <li>• Co-disposed with waste rock in Whale Tail WRSF</li> </ul>

**SECTION 3 • WATER MANAGEMENT PLAN AND WATER BALANCE**

---

**3.1 General Water Management Strategy****3.1.1 Water Management Objectives and Strategies**

The main objectives pertaining to water management for Project are to limit and/or stop the flow of surface water runoff in the pit and to limit the impact on the local environment. The key objectives for water management are:

- keep the different water types (i.e., contact, non-contact, and freshwater) separated to the extent practical;
- control and minimize contact water through diversion and containment;
- minimize freshwater usage by recycling and reusing the contact water to the extent practical; and
- meet discharge criteria before any site contact water is released to the downstream environment.

To achieve the above water management objectives, the following key strategies were implemented to develop the surface water Management Plan:

- Two levels of catchment disturbance have been defined for the area, namely undisturbed and disturbed. Areas that have been disturbed as part of the mine development are considered disturbed catchments, while the areas left unaffected are considered undisturbed catchments.
- For the purpose of mine water management, runoff from undisturbed areas is considered non-contact water, while runoff from disturbed catchment areas is considered contact water. Surface water that is diverted around the mine facilities, or groundwater that does not emerge into a mine facility, is considered non-contact water. Any non-contact water that mixes with contact water becomes contact water.
- Conveyance and storage of contact water will be controlled by channels and containment structures (i.e., sumps and ponds). Sumps will be installed in the open pits and in low points surrounding the open pits. Contact water will be diverted and collected in various sumps and water collection ponds and conveyed to an Attenuation Pond. Two attenuation ponds are planned for surface water and include the Whale Tail Pit Attenuation Pond and the IVR Attenuation Pond at former Lake A53.
- The IVR Attenuation Pond will contribute in reducing the operational water head in the Whale Tail Attenuation Pond. This will allow:
  - decreased operational risks (i.e. ice build-up above ramp and pit wall stability)
  - decreased overall volume of contact water and decrease global Arsenic (As) loading (less groundwater will flow in the pit and get in contact with PAG/ML material)

- improved operation efficiency (reduce ice build-up beside the ramp that could reduce operation ramp width – keep double lane instead of having a single lane to keep a safe distance from the seepage area during winter time – observed previously at Goose Pit)
- The collected water will be treated if the water quality does not meet the discharge criteria established in the Water Licence 2AM-WTP1830.
- The treated water will be reused as much as possible for mining and site operations to minimize the freshwater requirements. The excess treated water will be discharged into Lake A16 (Mammoth Lake) through a submerged diffuser or through a diffuser in Whale Tail Lake (South Basin) or other alternatives.
- Non-contact water will be intercepted and directed away from disturbed areas by means of natural catchment boundaries and/or man-made diversion structures or pumping systems and will be allowed to flow or to be discharged to the neighbouring waterbodies.

Underground development groundwater and contact water will be managed separately from surface infrastructure contact water. For underground water management, water management infrastructure was defined based on the following underground water management guideline principles:

- It is not currently planned to mine in the permafrost. It is an opportunity that will be further studied
- Heating is required when mining below top of cryopeg
- Brine needed until cryopeg elevation is reached (-275m)
- Contact and non-contact UG water not segregated – segregation is an opportunity
- Grouting is a mitigation measure during development (not included in hydrogeological model)
- UG storage stope (used to recycle UG water) – delay treatment, needed early
- Recirculation of brine during mining operation
- Limit addition of freshwater (used only for CRF, promote use of natural groundwater for operation)
- Treatment of UG saline water is not required if mining stay in the permafrost

The key strategies detailed below were implemented to support the underground water management:

- A Groundwater Storage Pond system (GSP) is designed to capture TDS (salt) affected waters. Up to three GSPs are planned to provide operational flexibility and adaptive management opportunity. GSP-1 and is used to store high salinity water from early mining operations through the permafrost. GSP-2 is used to store low salinity water,. A potential third pond (GSP-3) is planned for contingency

- Excess water volumes in the mine will be managed through the Underground Mine Stope and GSP-1 and GSP-2. Excess water volumes may also be managed with GSP-3 planned for contingency, operational flexibility, and adaptive management opportunity
- The Project has been planned with contingency water management storage to manage contact water during upset conditions. For example, GSP-3 could be used for temporary storage when not used for saline water management. This storage has sufficient capacity to manage the potential water quantity exceedances occurring during the freshet and can be used to hold excess contact water temporarily until it can be treated by the water treatment plant during the remaining open water season (July to September). During this time, at maximum capacity, the excess water can be treated and discharged within two weeks.
- At the end of underground mining, any remaining water in GSP ponds will be pumped underground for flooding of the underground workings

### 3.1.2 Water Management System

The water management system includes contact water collection ponds, freshwater collection ponds, diversion channels, retention dikes, culverts, water treatment plants for effluent, potable water treatment plant, sewage treatment plant, and discharge diffusers (as listed in Table 3.2). These various components are identified in Appendix A.

The water management system includes the following components (identified in Appendix A):

- four contact water collection ponds (Whale Tail Attenuation, IVR Attenuation, Whale Tail WRSF, plus the GSP Ponds);
- a temporary staging sump for WT Pit contact water dewatering (Quarry 1);
- two surface water collection ponds (Whale Tail Lake (South Basin) and Mammoth Lake);
- two water diversion channels (South Whale Tail Channel, and IVR diversion channel);
- four water retention dikes (Whale Tail, Mammoth, Whale Tail WRSF, and the IVR dikes once built);
- Culverts
- a freshwater intake causeway and pump system;
- a WTP and associated intake causeway;
- a Sewage Treatment Plant (STP);
- pipelines and associated pump systems;
- a Potable WTP;
- discharge diffusers located in Mammoth Lake and Whale Tail South

Additional water management system components have been or will be put in place at the Whale Tail Project, in order to adapt effectively to the site conditions and to manage non contact water adequately. The following components are part of the to the global water management system:

- a pumping system from Whale Tail South to Mammoth Lake; and
- the Whale Tail Dike seepage collection system;

Additional details on the water management system components are presented in section 3.1.4 of this plan.

**3.1.3 Waterbody Inventory**

The A and C watersheds will potentially be impacted by mining activities, primarily by dewatering of Whale Tail Lake (North Basin) to Lake A16 (Mammoth Lake), the Northeast Diversion to the C watershed, and the Whale Tail Lake (South Basin) Diversion to Lake A16 (Mammoth Lake). Waterbodies directly impacted by mining activities are presented in Table 3.1 and shown in Appendix A. The treated effluent discharge period for Lake A16 (Mammoth Lake) began in the second dewatering phase of the project in June 2019 and will continue throughout mine operations and into closure.

**Table 3.1 Inventory of Waterbodies Directly Impacted by Mining Activities**

Watershed	Primary Disturbance	Waterbody	Note
A	Dewatering	Lake A17	Dewatering of Lake A17 (Whale Tail Lake) to Whale Tail Lake (South Basin)
	IVR Pit	Lake A46	Part of the IVR Pit footprint
		Lake A47	Part of the IVR Pit footprint
		Lake A49	Part of the IVR Pit footprint
		Pond AP-67	Part of the IVR Pit footprint
		Pond AP-68	Part of the IVR Pit footprint
	IVR WRSF Placement	Lake A50	Covered by IVR WRSF
		Lake A51	Covered by IVR WRSF
		Lake A52	Covered by IVR WRSF
		Pond A-P21	Covered by IVR WRSF
	Whale Tail Lake (South Basin) Diversion	Lake A18	Flooded
		Lake A19	Flooded
		Lake A20	Flooded
		Lake A21	Flooded
		Lake A22	Flooded
		Lake A45	Part of diversion channel
		Lake A55	Flooded
		Lake A62	Flooded
		Lake A63	Flooded
		Lake A65	Flooded
Pond A-P1		Flooded	
Pond A-P53	Flooded		

Watershed	Primary Disturbance	Waterbody	Note
	Various Water Management Activities	Lake A17 (Whale Tail Lake)	Whale Tail Lake (North Basin) used as the Whale Tail Attenuation Pond Whale Tail Lake (South Basin) receives dewatering flows during dewatering activities, and discharge of treated effluent
		Lake A16 (Mammoth Lake)	Receives discharge of treated effluent
		Lake A53	Used as the IVR Attenuation Pond
		Lake A50	Covered by a Groundwater Storage Pond
C	Water Intake	Lake A16 (Mammoth Lake)	Sourced during operations for emulsion plant
		Lake C38 (Nemo Lake)	Sourced during operations
		Lake A17 (Whale Tail Lake)	Whale Tail Lake (South Basin) sourced during closure

**3.1.4 Water Management Plan During Construction and Operations**

*3.1.4.1 Infrastructure Required for Mine Site Water Management*

During the mine construction, operational, and closure phases, a network of collection and interceptor channels and sumps will be constructed and maintained to facilitate mine site water management. A list of the water management control structures and facilities is presented in Table 3.2 together with the proposed construction schedule. These structures were designed according to design criteria presented in the Appendix K: Project Design Considerations of the Water Licence 2AM-WTP1826 amendment, submitted to the NWB in May 2019. Final design details of these structures will be provided to the regulators for approval at least 60 days prior to construction.

Water management strategy updates were also communicated in August and September 2019 to the Nunavut Water Board regarding changes to the management of non-contact water for specific areas of the project. Those changes are reflected in Table 3.2.

Appendix A shows the location of the main structures at the different development stages of the mine life. Information on operation, maintenance, and surveillance (OMS) of Project dikes is provided in the following sub-sections.

**Table 3.2 Water Management Facilities and Construction Schedule**

Mine Year	Figure	Water Management Facilities Constructed or Installed
Year -1 (2018) Construction	-	<ul style="list-style-type: none"> <li>• Turbidity Curtains installation for dike construction</li> <li>• Start Whale Tail Dike</li> <li>• Construction of the low-permeability access road built of overburden and collection sump for Stage 1 WRSF</li> <li>• Freshwater intake causeway in Nemo Lake</li> </ul>

WRSF = Waste Rock Storage Facility.

**3.1.4.2 Dike Construction**

**Infrastructures Under Whale Tail Pit Project**

The following sections briefly describe the various dikes constructed for the Project. Information regarding the operation, surveillance, and maintenance of these structures is contained in the OMS Manual – Whale Tail Water Management Infrastructures (Agnico Eagle, 2021c). Additional information regarding construction of the dikes including all design drawings and figures, can be found in the As-built reports created and submitted for each structure.

Agnico Eagle will continue to identify and assess the water infrastructure performance issues to ensure efficient water management. A lesson learned exercise on the 2019 freshet was performed in 2020 and was used to improve water management practices and plans for 2020 and beyond. As a result, the 2020 open water season was considerably less problematic than 2019.

Whale Tail Dike

The WTD was constructed to raise Whale Tail Lake (South Basin), Lake A18, Lake A19, Lake A20, Lake A21, Lake A22, Lake A55, Lake A62, Lake A63, Lake A65, Pond A-P1, and Pond A-P53, to an elevation of 156.0 metres above sea level (masl), and divert runoff downstream to the Lake A16 (Mammoth Lake) watershed through the Whale Tail Lake (South Basin) diversion channel (SWTDC). Whale Tail Dike is a zoned rockfill dike constructed on the lakebed foundation with a core composed of a fine filter dynamically compacted. A coarse filter was placed between the rockfill and the fine filter. A cement-bentonite cut-off wall consisting mainly of secant piles was constructed through this dense core and acts as a seepage barrier.

Whale Tail Dike Seepage

The Whale Tail Dike was commissioned on March 5, 2019 with the beginning of the dewatering activity of the North Basin. During the construction of the dewatering ramp extension in April 2019, the pumping was interrupted. During that time, a decrease of the water level was observed in the South Basin (upstream) and an increase of the water level on the North Basin (downstream). Seepage was identified as a probable cause for these observations.

In July 2019, the seepage flow was measured using v-notch weirs at approximately 300 m<sup>3</sup>/h which is higher than what was anticipated in the water balance. A detailed investigation including additional instrumentation and geophysics was conducted for a better understanding of the seepage phenomenon at the Whale Tail Dike. In 2020, a pumping system was installed to collect and manage the seepage water prior reaching Whale Tail Attenuation Pond, as presented in section 3.1.4.18 of this report, with the objective of returning water to the environment if water quality allows.

In 2020, Agnico Eagle conducted an intensive grouting campaign to reduce the seepage flow. Following the dike grouting campaign, the seepage flow, measured using v-notch, has significantly decreased to approximately 80 m<sup>3</sup>/h and it was concluded that the seepage reduction objective of the grouting campaign was successfully reached. Agnico Eagle continues to closely monitor the situation.

#### Mammoth Dike

The Mammoth Dike was constructed to protect the mine site area from potential backwatering from Lake A16 (Mammoth Lake) during the operational and closure phases. Mammoth Dike has a length of about 330 m and a height of 2 m. The Mammoth Dike is a rockfill dike lined with bituminous geomembrane on its upstream face encapsulated at the toe in a layer of fine filter amended with bentonite (FFAB) liner in turn constructed in a key trench. The key trench extends down to the bedrock on most of the dike length. A thermal berm of rockfill was placed on top of the key trench during the winter season to prevent the FFAB from thawing.

#### Whale Tail WRSF Dike

The WRSF Dike confines contact water in the Whale Tail WRSF Pond before it is pumped to the Whale Tail Attenuation Pond. The WRSF dike is about 360 m long and 5 m high. The Whale Tail WRSF Dike is a rockfill dike with a bituminous liner on its upstream face encapsulated at the toe in a layer of FFAB liner in turn constructed in a key trench. The FFAB liner takes advantage of frozen soil conditions to integrate the permafrost into its foundation (and key trench).

On August 2019, seepage from WRSF Pond reported through this structure to Mammoth Lake inducing tension cracks on the crest of the structure. Immediate actions taken were to build an access road to the downstream portion of the dike, in order to excavate a small sump and pump the seepage water into WRSF pond. Furthermore, WRSF Pond was emptied and maintained dry. Downstream pumping stopped on September 30<sup>th</sup>, when the reporting flow and surrounding had frozen. In October 2019, the KIA conducted a sample analysis of the lake bed sediments in Mammoth Lake. The report concluded the seepage did not have a measurable impact on metal quantities of the Mammoth Lake sediments (McDougall et al. 2019).

A series of measures were implemented by Agnico to minimize the risk of future similar events occurring in this location:

- Operational water level were reviewed to keep water as low as possible in the WRSF pond recommended by the Meadowbank Dike Review Board (MDRB);
- Aggradation of permafrost into the dikes foundation by:
  - Construction of a thermal berm in 2020 on the upstream portion of the dike;
- Access road to the downstream area was constructed to facilitate inspection ;
- A downstream water collection system was designed and constructed;
- Various environmental monitoring programs:
  - Monthly limnology profile of Mammoth Lake during winter and open water conditions;
  - Mammoth Lake to be included in a Core receiving environmental monitoring program; and
  - A sediment sampling campaign to be executed at Mammoth Lake.

Additional details on this event can be found in the letter submitted on December 20, 2019 to Environment and Climate Change Canada. Agnico Eagle continues to closely monitor the situation. No seepage was observed in 2020 which confirmed the adequacy of the mitigation measures implemented to ensure adequate performance of the structure

#### Northeast Dike

The North East (NE) Dike was a temporary structure is designed to prevent runoff from the Northeast watershed reporting to the Whale Tail Pit and to divert them to Nemo Lake. The upstream slope of the NE Dike is lined with bituminous geomembrane encapsulated at the toe in a layer of FFAB liner in turn constructed in a key trench to an ice-poor till foundation.

Following the fish out and dewatering of surrounding lakes (A46 & A47) in 2020, this structure was dismantled as part of the IVR pit development.

#### **Infrastructures Under Expansion Project**

During the Expansion Project, flow of surface water into the Whale Tail Pit will continue to be controlled by Whale Tail Dike and Mammoth Dike. Flow of surface water into IVR Pit will be controlled by the IVR Diversion and IVR Attenuation Pond Dikes. Construction mitigation measures and construction methods of the A53 Dikes are consistent with measures and methods for dike construction of approved infrastructure (above). In 2020, the Lake A53 catchment remained at baseline conditions until it became the IVR Attenuation Pond following fishout and dewatering completion. IVR Attenuation Pond dike construction is planned in 2021 prior freshet. The IVR Attenuation Pond will be operational by freshet 2021.

It should be noted that no details on IVR Dike are presented in this report, as this infrastructure was under detailed engineering design in 2020. Information will be added in the plan once the structure is commissioned.

### 3.1.4.3 Dewatering

As per Type A Water Licence 2AM-WTP1830, Agnico Eagle initiated the dewatering of Whale Tail Lake (North Basin) in 2019 following the construction of the dike and the fish out. To allow the mining of the Whale Tail Pit, Lake A17 (Whale Tail Lake) was partly dewatered following the Whale Tail Dike construction.

The estimated total volume of Whale Tail Lake (Lake A17) is 8.5 million m<sup>3</sup> (Mm<sup>3</sup>). The dewatering started early March 2019. A total of 2,148,542 m<sup>3</sup> of water was discharged directly to Whale Tail Lake South Basin without requiring treatment. The second phase of dewatering started in mid June 2019 discharging to Lake A16 (Mammoth Lake). For this phase of dewatering, water from the North Basin was treated via the TSS removal unit of the WTP and discharged in Mammoth Lake through the diffuser.

Once the dewatering phase was completed in Q2 2020, part of the North Basin located outside the Whale Tail Pit footprint became the Whale Tail Attenuation Pond. The Whale Tail Attenuation Pond is since used to receive contact water from different sumps and ponds around site.

Waterbodies and ponds within the footprint of the IVR Pit, IVR WRSF and IVR Attenuation Pond required dewatering in 2020. To allow the mining of the IVR Pit, lakes A46, A47 and A49 were dewatered in 2020. Following fish out completion, lakes inside IVR pit mining footprint were dewatered and transferred into Whale Tail Attenuation Pond representing a total approximate volume of 215,000 m<sup>3</sup>.

Similar process mentioned above was also used to dewater the waterbodies inside IVR WRSF footprint (AP-21, A50, A51 and A52). The water was discharged into lake A53 once its fish out was completed for a total approximate volume of 38,000 m<sup>3</sup>.

Similar to the Whale Tail (North Basin) dewatering process, approximately 2/3 of the dewatered water from Lake A53 was pumped and directly discharged to Whale Tail Lake (South Basin). The remaining 1/3 of the water was processed through the WTP during open water conditions. The complete dewatering of A53 represents a total approximate volume of 213,000 m<sup>3</sup>. The IVR Attenuation Pond is intended to manage all contact water from 2021 to closure while discharging through the O- WTP during open water conditions.

### 3.1.4.4 Key Water Management Activities during Construction and Operations

An inventory of waterbodies impacted by mining activities is provided in Table 3.1 (Section 3.1.3) and the water management facilities required for the Plan is provided in Table 3.2 (Section 3.1.4.1). These tables should be read in conjunction with Table 3.3, which presents the yearly major water management activities during the construction and operational phases. Water management activities during the closure phase are described in Section 3.2.

Any water requiring treatment will be pumped to the water treatment plant(s) prior to discharge through the diffuser in Mammoth Lake or through the diffuser in Whale Tail Lake (South Basin) or other alternatives. The latter are outlined in the Whale Tail Pit Expansion Project Adaptive Management Plan (Table 3: Receiver Water Quality Adaptive Management Strategy). The plan is currently under the NWB approval process. The other alternatives for discharge are Lakes D1 and D5 in the case that Level 3 is reached (high risk situation in the receiver water quality). Discharging in Lakes D1 or D5 would require a complete assessment of potential discharge, with approval from the NWB as per NIRB Project Certificate Conditions.

Water collected in the Whale Tail Attenuation Pond and/or IVR Attenuation Pond will be reused to the extent practical in the open pit and dust control operations, and the excess water will be treated by the WTP prior to discharge to the receiving environment.

Non-contact water will be diverted away from the mine site infrastructure by reversing natural flows or by using diversion channels and culverts.

Freshwater usage on site will be supplied from Lake C38 (Nemo Lake) and from Lake A16 (Mammoth Lake) during operations, and from Whale Tail Lake (South Basin) during closure.

In the amended Water Licence the permitted freshwater sources are Nemo Lake (all purpose), Lake D1 (Re-flooding of Whale Tail Pit, IVR Pit, Underground mine, and Whale Tail (North Basin) and associated use, or as otherwise approved by the Board in writing), Whale Tail South (Re-flooding of Whale Tail Pit, IVR Pit, Underground mine, and Whale Tail (North Basin) and associated use, or as otherwise approved by the Board in writing).

**Table 3.3 Water Management Activities During Construction and Operations**

Mine Year	Water Management Activities and Sequence
Year -1 (2018)	<ul style="list-style-type: none"> <li>• Temporarily pump contact water from the Stage 1 WRSF sump to Quarry 1</li> <li>• Temporarily pump contact water from the starter pit, construction, ore stockpiles, industrial sector, and main camp sector to Quarry 1</li> <li>• Treat turbid water from construction using the construction WTP and discharge in Whale Tail North</li> <li>• Pump STP effluent to Whale Tail Lake (North Basin)</li> <li>• Freshwater intake initially located in Whale Tail Lake (South Basin); moved to Lake C38 (Nemo Lake)</li> </ul>
Year 1 (2019)	<ul style="list-style-type: none"> <li>• Dewatering of Whale Tail Lake (North Basin) to Whale Tail South Basin and Mammoth Lake (through the WTP)</li> <li>• Pump contact water from the open pit to Quarry 1</li> <li>• Pump contact water from the Whale Tail WRSF Pond to Quarry 1</li> <li>• Treat through the WTP the Whale Tail North Water above discharge limit and discharge in Lake A16 (Mammoth Lake)</li> </ul>

Mine Year	Water Management Activities and Sequence

WRSF = Waste Rock Storage Facility; WTP = Water Treatment Plant.

Table 3-4 presented below summarizes the overall contact water management plan for the major mine infrastructure with the initial water collection location and final water destination. Note that all contact water was sent to the Whale Tail Attenuation Pond in 2020. In 2021, during freshet, a transition phase will be established to move most contact water collection location’s discharges from Whale Tail Attenuation Pond to IVR Attenuation Pond. Detailed water management information for major mine infrastructure areas is described in the following sub-sections. Water management of the non-contact water on site is also presented in section 3.1.4.18. Water management flowsheets for the construction and operations phase are provided in Appendix B.

**Table 3.4 Overall Site Surface Contact Water Management Plan**

Contact Water Source	Initial Contact Water Collection Location	Final Contact Water Collection Location
Industrial Sector	Whale Tail Attenuation Pond	IVR Attenuation Pond (primary)  Whale Tail Attenuation Pond (secondary)
Whale Tail and IVR WRSFs Sector	Whale Tail WRSF Ponds IVR WRSF collection system	
Ore Stockpiles	Whale Tail Attenuation Pond	
Landfill	Whale Tail WRSF Pond	
Open Pits (Whale Tail and IVR)	Open pit sumps	

WRSFs = Waste Rock Storage Facilities.

*3.1.4.5 Erosion and Sediment Control Plan*

As described in the previous sections, Project site infrastructure, channels, sumps, and associated water management activities are designed with consideration of site wide erosion and sediment control. In addition to design controls, best management practices (BMPs) will furthermore ensure that activities, practices, devices or a combination thereof will prevent or reduce the release of sediments and will control erosion. The selection of permanent or temporary BMPs will be specific to the site and timing and may require regulatory approval prior to installation or construction.

Temporary BMPs for Whale Tail and IVR Pits may include:

- Silt fences and fabric installation
- Turbidity curtains
- Sediment control basins to detain sediment-laden water
- Diversion of flows away from the construction area

Permanent BMPs at the Whale Tail and IVR Pits may include:

- Infiltration basins and trenches
- Sedimentation basins or ponds
- Construction of swales in ditches

Monitoring of erosion and sedimentation associated with construction and operations are discussed in Section 3.2 of this plan and are detailed in the Water Quality and Flow Monitoring Plan (Agnico Eagle, 2019), and dike construction sediment control and monitoring is presented in the Dike Construction and Dewatering Management Plan (Agnico Eagle, 2020).

For specific details on sediment control guidelines and license requirements, on erosion monitoring and mitigation during freshet and the rise of water level in the South Basin of Whale Tail Lake, refer to the Whale Tail Project - Erosion Management Plan (Agnico Eagle, 2018b).

#### *3.1.4.6 Whale Tail Attenuation Pond*

One of the main contact water ponds of the project (i.e., Whale Tail Attenuation Pond) is located in a deep part of Whale Tail Lake (North Basin), following the dewatering of the North Basin. Until freshet 2020, Quarry 1 was used as main contact water pond for the Whale Tail site. During freshet 2020, contact water from the major mine infrastructure was diverted and/or collected in the Whale Tail Attenuation Pond. Contact water from the Whale Tail WRSF Pond and runoff water in the open pit collected by sumps was also pumped to the Whale Tail Attenuation Pond.

The excess water is treated by the WTP for TSS and arsenic if required prior to discharge to the receiving environment via the diffuser into Lake A16 (Mammoth Lake) or Whale Tail South. Water quality objectives for arsenic and phosphorous was met via the diffuser design: 10 ports at 12.6 m spacing, 75mm diameter diffuser ports, and effluent mixing (mixing zone).

For 2021, Whale Tail Attenuation Pond will remain one of the main contact water ponds for the project. However, excess water will be transferred to IVR Attenuation Pond.

#### *3.1.4.6 IVR Attenuation Pond*

The other main contact water pond of the Project (i.e., IVR Attenuation Pond) will be in a deep part of former Lake A53, following the A53 dewatering and IVR dike construction. Contact water from the IVR WRSF collection system will be pumped to the IVR Attenuation Pond.

The maximum operating level for normal condition is set at El. 163.2 at all time. The normal operating level will be set at a lower elevation based on operational strategy. Details on the operating level can be found in the OMS manual for the Whale Tail Water Management Structures (AEM, 2021).

Excess water will be treated by the WTP for TSS and arsenic if required prior to discharge to the receiving environment via the diffuser into Lake A16 (Mammoth Lake) or Whale Tail South.

Monitoring of the effluent discharge to Mammoth Lake or Whale Tail South is done as per the Water License requirement and is detailed in the Whale Tail Pit Water Quality and Flow Monitoring Plan.

#### *3.1.4.7 Water Management in Whale Tail Waste Rock Storage Facility*

The Whale Tail WRSF will be used to permanently store all waste rock and overburden from mining activities.

Seepage and runoff from the Whale Tail WRSF during the construction and operational phases will be managed via the Whale Tail WRSF Pond, isolated by the Whale Tail WRSF dike, where the contact

water was pumped to the Whale Tail Attenuation Pond for further treatment until 2021 (i.e., when the IVR Attenuation Pond becomes operational), and to the IVR Attenuation Pond

Runoff from the ultimate footprint of Whale Tail WRSF will report to the Whale Tail WRSF Contact Water Collection System and the IVR Pit.

All overburden soils will be stabilized with waste rock berms in order to limit spreading and soil water separation. More details about management of the Whale Tail WRSF are presented in the Mine Waste Rock and Tailings Management Plan.

In April 2019, O’Kane Consultants developed a landform water balance model for the Whale Tail and IVR WRSFs (OKC, 2019). Information on the landform water balance model can be found in the report referenced in the management plan (OKC, 2019). The objective of the landform water balance was to estimate the runoff, interflow, and basal seepage rates for different slopes and aspects of the Whale Tail and IVR WRSFs.

#### *3.1.4.8 Water Management in IVR Waste Rock Storage Facility*

The IVR WRSF is in operation since the IVR Pit was initiated.. Anticipated runoff from the IVR WRSF during freshet 2021 will be sent to the IVR Attenuation Pond. The total catchment of the IVR WRSF increases proportionally with the increase in waste rock footprint.

#### *3.1.4.9 Water Management for Overburden Storage*

The overburden storage is located within the catchment of the Whale Tail Attenuation Pond as shown in Appendix A. Based on the topographic information, contact water will naturally flow to the Whale Tail Attenuation Pond for further treatment. Channels will be constructed if deemed required.

#### *3.1.4.10 Water Management for Ore Stockpile Areas*

The ore stockpiles are located within the catchment of the Whale Tail Attenuation Pond as shown in Appendix A. Based on the topographic information, contact water will naturally flow to the Whale Tail Attenuation Pond for further treatment. Channels will be constructed if deemed required and water management systems (i.e. pump, piping, etc) will be installed to direct the seepage and runoff to the pond.

The Ore Stockpiles are designed based on the following considerations. A cover of overburden and/or waste rock was placed over original ground to reduce any thaw-induced differential settlements. Waste rock was then placed to follow the natural topography, thereby reducing the likelihood of water ponding on the surface of the pad requiring additional maintenance. A final grade of about 0.5% sloping towards the Whale Tail Attenuation Pond was achieved. Any surface run off from the ore stockpile or the pad will therefore be directed to the Attenuation Pond containment area.

#### *3.1.4.11 Water Management for Quarry 1*

Prior to commissioning of the Whale Tail Attenuation Pond, contact water collected from the Stage 1 WRSF sump, from the starter pit, construction, and industrial sectors was pumped to Quarry 1.

The contact water from Quarry 1 was pumped to Mammoth Lake without treatment when the water quality met discharge criteria. The discharge was done via the permanent diffuser in Mammoth Lake. If needed, water was treated via the Water Treatment Plant to meet discharge criteria.

Water quality monitoring follows the requirements of the Water License 2AM-WTP1830. Discharge from Quarry 1 ceased in May 2020.

#### *3.1.4.12 Water Management for the Whale Tail Open Pit Sector*

The Whale Tail open pit is planned to extend to approximately 300 m below the ground surface. The open pit will be mined mostly within permafrost except for the north-central portion of the pit which will be within the closed talik at the northern end of Lake A17 (Whale Tail Lake). The pit does not extend through the bottom of the closed talik; however, the open pit acts as a sink for groundwater flow during operations, with water induced to flow up through the open talik beneath the central portion of Lake A17 (Whale Tail Lake) and into the open pit. Accordingly, groundwater inflows into the open pit are expected; this water will be mixed with the open pit contact water and pumped to the IVR Attenuation Pond and/or Whale Tail Attenuation Pond for further treatment.

Once mining intersects the closed talik, the groundwater inflow to the pit is predicted to be 1,140 m<sup>3</sup>/day. The overall inflow to the pit is not expected to decrease significantly as the pit deepens because the flow of water is primarily through the permeable weathered bedrock and because the lower portion of the pit is in permafrost. It is important to note that most of the volume is expected to be due to residual water that remained and lakebed sediment drainage as the pit expanded into dewatered section of the Whale Tail North Basin. In 2021, the pit will continue to expand eastward and south. While most of the expansion is projected to be excavated in winter time, some sediment drainage is expected during the 2021 summer.

Groundwater inflow predictions during operations conservatively assume that no freeze-back will occur in the pit walls during mining. This assumption was adopted for Whale Tail Pit to be conservative and because during the first few years of mining, the pit will be both widened and deepened, resulting in the continual exposure of unfrozen bedrock. During the later years of mining; however, the pit development will be entirely within the permafrost and significant freeze back in the pit walls is considered possible and has been observed at Meadowbank. Although not simulated, if freeze back does occur as is the case at Meadowbank, actual groundwater inflow to the pit could be significantly lower.

Additional details on the most recent site water balance are presented in Section 3.3 of this plan.

TDS concentration in the groundwater inflow to the pit was predicted to decrease during mining. The relatively low TDS concentration and decrease in TDS over time reflects the minimal upwelling of higher salinity waters at depth due to the presence of the permafrost at the base of the pit and the high contribution of lake water and Whale Tail Attenuation Pond water.

#### *3.1.4.13 Water Management for the IVR Open Pit Sector*

The IVR Pit is located just north of Whale Tail Lake, within the Northeast Sector in the permafrost environment, thus no groundwater inflows are predicted. Water management infrastructures are designed to only manage runoff water reporting to the pit during freshet. The IVR Pit was initiated in Q3 2020. Its operational runoff is conveyed to the active attenuation pond (i.e. IVR Attenuation Pond).

#### *3.1.4.14 Water Management for Haul Roads*

A network of access and haul roads will connect the ore body to the Whale Tail and IVR WRSF Sector and the Industrial Sector. Most of the roadways servicing the mining area will drain directed towards the proposed contact water management infrastructure. Detailed information on roads is described in the Whale Tail Pit Haul Road Management Plan.

The approach to water management for these roads will involve the implementation of local best management practices during the construction, operational, and closure phases. The roads are constructed of non-potential for acid generating and non-leaching waste rock from mining operations. Other best management practices will strive to minimize the amount of runoff originating from the roadways and to prevent the migration of surfacing material from the roadways and crossings. Any areas identified as point sources of runoff originating from the roadways or crossings can be managed locally with silt fences, straw booms, turbidity curtains, interceptor channels, rock check dams, and/or small sedimentation ponds.

#### *3.1.4.15 Water Management for Landfill*

The landfill is located southeast of the Whale Tail WRSF, within the catchment of the Whale Tail WRSF Pond, as shown in Appendix A. Based on the topographical information, runoff and any seepage from the landfill will naturally flow to the Whale Tail WRSF Pond and then be pumped to the Whale Tail Attenuation Pond for further treatment before discharge.

Further information on the management of this facility is described in the Whale Tail Pit Landfill and Waste Management Plan.

#### *3.1.4.16 Sludge and Brine Management from Water Treatment Plants*

This section summarizes water treatment requirements and is extracted from the Mean Annual Water Balance and the Mine Site and Downstream Receiving Water Quality Predictions, from Golder Associates, both dated May 2019. Any water requiring treatment will be pumped to the water treatment plant(s) prior to discharge through the diffuser in Mammoth Lake or through a diffuser in Whale Tail Lake (South Basin) or other alternative discharges.

Sludge disposal will be done in the Whale Tail WRSF.

#### OPERATION WATER TREATMENT PLANT (WTP)

The arsenic and TSS water treatment plant (WTP) was commissioned at the beginning of May 2019, to treat the final dewatering volumes from Whale Tail Lake (North Basin). This plant is used to treat surface water for TSS and Arsenic before discharging to approved diffuser. The arsenic water treatment unit has not been required so far.

Sludge water from the Operation Water Treatment Plant (OWTP) is dewatered with a centrifuge to produce a cake having a density with 20% of solid content. This cake will be stored in the Whale Tail WRSF. The maximum predicted annual volume of cake from the OWTP is approximately 5,760 cubic metres (m<sup>3</sup>).

#### TDS WATER TREATMENT PLANT (S-WTP)

The S-WTP is not needed according to the latest water balance as the current underground mining plan is designed to minimize the inflows requiring TDS treatment by staying in the permafrost. The S-WTP would include a TDS Treatment plant if required.

The concept for the TDS Treatment plant would be to treat low salinity water that is stored in the GSP-2 until closure. The TDS Treatment plant would be active only from June through September. The permeate would be combined with the WTP effluent for discharge from site. The brine produced from the TDS Treatment plant would be stored in GSP-1. The S-WTP could also include two Desalination units, which would treat water stored in GSP-1. The salt solid produced from treatment would either be used at site and/or shipped off site, and the permeate would be combined with WTP effluent for discharge from site.

Agnico Eagle is currently developing an Underground Project limited into the permafrost only. This change results in no more treatment and discharge of saline water to Whale Tail Lake. The water management strategy for underground water would only be based on storing water in GSP-1 and GSP-2. High and low salinity water would not be segregated anymore. At closure, the water from GSP1 and GSP2 will be sent underground.

#### *3.1.4.17 Underground Water Management*

Underground development groundwater and contact water will be managed separately from surface infrastructure contact water. For underground water management, the following key strategies were implemented to develop the underground water Management Plan:

- A Groundwater Storage Pond system (GSP) is designed to capture TDS (salt) affected waters. Up to three GSPs are planned to provide operational flexibility and adaptive management opportunity.

- Excess water volumes in the underground mine will be managed through the Underground Mine Stope and GSP-1 and GSP-2. Excess water volumes may also be managed with GSP-3 planned for contingency, operational flexibility, and adaptive management opportunity
- At the end of underground mining, any remaining water in the GSP ponds will be pumped underground for flooding of the underground workings

#### *3.1.4.18 Non-Contact Water Management*

In order to adequately manage non-contact water on site, some passive flows have been substituted with a pumping alternative that complies with the original intent of the approved water balance and Water License 2AM-WTP1830 (same origin and destination of water). Those systems were proposed as adaptive management methods, in response to the encountered site conditions during open water season and the high volume of precipitation received, resulting in additional volume of water to manage.

The actual non-contact water management systems put in place in summer 2019 and 2020 are described below.

#### North-East Pond to C-watershed

The non-contact water from the North-East (NE) Pond watershed was initially planned to overflow by gravity toward Nemo Lake once the North-East Dike is operational. During a routine inspection in July 2019, it was observed that the topography toward Nemo Lake would not allow water to overflow naturally before overtopping the dike liner. Following this observation, water was pumped from NE Pond toward the project site, adding pressure on dewatering activity. The water from the NE Pond was then pumped to the tundra within the Nemo watershed (Water shed C). This system for water level management was operational in 2019 and 2020 prior de dewatering of the IVR footprint to manage water level in the NE Pond when required, until NE Dike was dismantled in late 2020.

#### North-East Sector Pond Management

During the summer of 2019 and 2020, significant water inflows from Lake A49 towards the Whale Tail Pit area were noticed. Maintaining the water elevation in Lake A49 throughout freshet was required to avoid the transformation of non-contact water (Lake A49 overflow) to contact water (pit water). The objective of this water transfer is to minimize contact water creation. Water was sent into the North-East Pond. Lakes A47 and A49 were then dewatered in 2020 as part of the IVR Pit development.

#### A53 Lake to Whale Tail South

The non-contact water from the A53 watershed was planned to be redirected to Whale Tail South through the East Channel.

Prior the dewatering phase, the water level in Lake A53 was maintained to the natural level by pumping exceeded volume to Whale Tail South as per previous approval from NWB. Regular water level monitoring was conducted at this time. The monitoring aligns with the Water License 2AM-WTP1830 requirements, Schedule I Table 2 for ST-WT-7 and as per Part F Item 7 for TSS limits.

Once the dewatering phase completed, as per explained in section 3.1.4.3 of this report, A53 became IVR Attenuation Pond.

#### Whale Tail South Discharge to Mammoth Lake

The non-contact water from Whale Tail South Basin was pumped to Mammoth Lake in 2019 as per approval from NWB. This pumping activity was required to manage and then maintain the water level in Whale Tail South Basin, in order to allow for the construction of the Whale Tail South Channel (SWTC) and preserve Whale Tail Dike integrity. This system temporarily substitutes passive flow via the SWTC with a pumping alternative that complies with the original intent of the approved water balance and Water License 2AM-WTP1830 (same origin and destination of water). This pumping activity also provides flexibility and adds robustness to the water management strategy. Discharge was completed via a diffuser to avoid erosion into Mammoth Lake. In 2020, no mechanical transfer from Whale Tail South to Mammoth Lake occurred but Agnico might re-use this system in the future to

#### Whale Tail Dike Seepage Discharge to Whale Tail South Basin

The non-contact water seeping from Whale Tail Dike (WTD) is collected into the seepage collection system before reaching the Whale Tail Attenuation Pond and then discharged to Whale Tail South Basin. The seepage collection system consists of 4 pumping wells where surface seepage is diverted into and that are deep enough to potentially collect most below surface seepage as well. This system allows to minimize volume of water reporting to Whale Tail Attenuation Pond. Details of the installation and the system will be compiled in the as-built report, which is in progress and will be completed once the system is fully commissioned.

Seepage water, collected from this system, can be discharged into the Whale Tail South Basin via a diffuser without treatment if the water quality meets the discharge criteria of the Water License 2AM-WTP1830. If discharge criteria are not met, water will overflow from the pump stations to the Whale Tail Attenuation Pond, and then will be pumped through the WTP for discharge.

Routine monitoring of the seepage water quality from each pump station will be as per the Water License 2AM-WTP1830 and the Metal and Diamond Mining Effluent Regulation (MDMER). This monitoring will allow Agnico Eagle to put mitigation measures (for example, treating the water via the WTP) in place if needed. Turbidity and pH will also be monitored.

In 2020, following the Whale Tail Dike grouting campaign, the seepage pH results indicated an increase above the acceptable limit indicated in the Water License 2AM-WTP1830. The seepage collected from the system was therefore pumped to Whale Tail Attenuation Pond.

In 2021, Agnico Eagle will closely continue to monitor the situation.

#### IVR Diversion Channel

This IVR Diversion channel has the intent to collect non-contact runoff water from the east side of the Nemo watershed and diverting by gravity the water to Nemo Lake. This infrastructure allows minimizing the volume of non-contact runoff water reporting to IVR pit area. IVR Diversion Channel construction has been completed in 2020. The 260m long channel has been excavated and then covered with multi layers of fine and coarse materials and with geotextiles which will allow minimizing TSS in water reporting to Nemo Lake. More details of the channel construction can be found in the as-built report (SNC, 2021).

2021 will be the first year of the channel's operation. For this reason, Agnico Eagle will closely monitor and inspect during the year this new infrastructure to ensure it will meet operational criteria and respect minimal TSS.

#### South Whale Tail Channel (SWTC)

Construction of South Whale Tail Channel has been completed in 2020 prior freshet. The SWTC connect Whale Tail South basin to Mammoth Lake. The 900 m long channel is approximately 5m wide at the base with lateral slope of 3H:1V. Once excavated, the channel has been covered with multi layers of coarse and fine materials, rip rap and layer of geotextiles to ensure minimal TSS in the flow reporting to Mammoth Lake and also preventing erosion. Also, at the outlet of the channel, a turbidity barrier was installed and will remain in place as a supplementary protection to avoid TSS flowing in Mammoth Lake. The channel allows to naturally control Whale Tail South water level without any mechanical transfer intervention. Details of the channel construction can be found in the as-built report (SNC, 2020).

In mid-June 2020, first flow was observed in the channel reporting to Mammoth Lake. In 2020, a total of 3.9 M m<sup>3</sup> have been reported flowing through this channel until mi-November when the inlet of the channel froze.

In 2021, routine inspections and monitoring will be executed to ensure channel continue to operate under normal conditions and to ensure minimal TSS reporting to Mammoth Lake.

### 3.1.5 Freshwater and Sewage Water Management

#### 3.1.5.1 Freshwater Management

The permitted freshwater sources as per the Water License 2AM-WTP1830 are Nemo Lake (all purpose), Lake D1 (Re-flooding of Whale Tail Pit, IVR Pit, Underground mine, and Whale Tail (North Basin) and associated use, or as otherwise approved by the Board in writing), Whale Tail South (Re-flooding of Whale Tail Pit, IVR Pit, Underground mine, and Whale Tail (North Basin) and associated use, or as otherwise approved by the Board in writing).

Freshwater usage includes potable use, fire suppression, dust suppression, drilling water (if contact water is not available), water for the emulsion plant, and water for the truck shop. The freshwater source is Lake C38 (Nemo Lake), and Lake A17 (Whale Tail Lake) during closure. For explosives mixing and associated use, the water is pumped from Lake A16 (Mammoth Lake), as per Part E, condition 1 of the Water License 2AM-WTP1830. Freshwater will also be required to refill Whale Tail Lake (North Basin) at closure and will be sourced from Lake D1 and inflows to Whale Tail Lake (North Basin). Agnico Eagle will endeavour to minimize the amount of freshwater required for the Project, where possible.

Freshwater is sourced through a freshwater intake and pump system. The intake consists of vertical filtration wells fitted with vertical turbine pumps that supply water on demand. The intake is connected to the pump house with piping buried under a rockfill causeway. The intake pipe exits at the bottom of the causeway and is fitted with a stainless-steel screen, as per Part E, condition 4 of the Water License 2AM-WTP1830. The rockfill causeway acts as a secondary screen to prevent fish from becoming entrained.

The stainless-steel screens design for the water intake is consistent with the Fisheries and Oceans Canada (DFO) "Freshwater Intake End-Of-Pipe Fish Screen Guideline" (DFO 1995). As per the DFO policy intake screens will be cleaned every 2 years. The freshwater intake will be moved to Whale Tail Lake (South Basin) at closure.

Freshwater is pumped to an insulated main storage tank located at the Whale Tail Camp. The freshwater pipeline is made of a high density polyethylene pipe and insulated and heat traced. The Whale Tail Camp has a Freshwater Treatment Plant (potable). In the Potable WTP, the freshwater first goes through sand filters and then is pumped through ultraviolet units, and finally treated with chlorine. The treated water is stored within a potable water tank. Potable water is monitored according to the Nunavut health regulations for total and residual chlorine and microbiological parameters. Treated potable water is piped to other facilities requiring potable water. Detailed plant operation specifications were provided in FEIS Volume 1, Section 1. 2.4.1.

Freshwater and potable water use is required during operations and additional freshwater will be required from Whale Tail Lake at closure. The current Type A Water Licence Part E Item 1 and 2 provides for a maximum quantity of water use not to be exceeded at 700,859 m<sup>3</sup> annually during

construction and operation as well as 14,855,606 m<sup>3</sup> annually during closure. The freshwater usage from Nemo Lake needs to respect the license limit of 209,544 cubic meter per year.

It is important to note that total annual withdrawals of water from Nemo Lake (209,554 m<sup>3</sup>/year) will remain well below the lake's annual inflow volume of approximately 476,000 m<sup>3</sup> (based on the mean annual water balance of the lake under baseline conditions), and ii) DFO's guideline of 10% of the under ice volume for the duration of operations (i.e., under-ice volume of 6,170,000 m<sup>3</sup> derived from FEIS Addendum Appendix 6-M submitted with the Whale Tail Pit - Expansion Project). Residual effects to fish and fish habitat are therefore expected to be negligible.

During closure, the Whale Tail and IVR Pits, the underground mine, and Whale Tail Lake (North Basin) will be allowed to flood naturally with non-contact water, treated water, freshwater from direct precipitation, runoff from adjacent land, and Whale Tail Lake (South Basin). It is anticipated that approximately 47,000,000 m<sup>3</sup> over 16 years from Whale Tail Lake is required to fill the mined-out Whale Tail Pit (i.e., approximately 55,000,000 m<sup>3</sup>), IVR Pit (i.e., approximately 10,000,000 m<sup>3</sup>), underground mine (i.e., approximately 1,000,000 m<sup>3</sup>) and Whale Tail Lake (North Basin) (i.e., approximately 6,000,000 m<sup>3</sup>) to its original level, representing approximately 2,900,000 m<sup>3</sup>/year from Whale Tail Lake (South Basin).

As per part E, condition 2 of the Water License 2AM-WTP1830, the use of water from Whale Tail Lake shall not exceed a total of 10,655,000 m<sup>3</sup>/year commencing when notification of closure is received by the NWB through to the expiry of the Licence. The limit for Nemo Lake is 14,672 m<sup>3</sup>/year and the limit for Lake D1 is 1,710,000 m<sup>3</sup>/year, both commencing when notification of closure is received by the NWB through to the expiry of the Licence.

#### *3.1.5.2 Sewage Water Management*

Sewage is collected from the camp and change-room facilities and pumped to a STP. The objective of the STP is to treat sewage to an acceptable level for discharge to the Whale Tail or IVR Attenuation Pond via a sewage water discharge pipeline. The STP is housed in a prefabricated (modular) structure located in the Whale Tail Camp. The sewage treatment system is designed based on the occupation maximum of the camp for 400 persons (240L per day and per person). The design average daily flow is 96 m<sup>3</sup>/day (4 cubic metres per hour [m<sup>3</sup>/hour]).

Previously, the sewage treatment plant at the Amaruq camp could accommodate 400 workers. With the addition of four wings to the Operations Camp for the project expansion, the total camp capacity was increased to 546 workers. An expansion of the sewage treatment systems was thus required. These systems are built with typical 40-foot containers.

No major change in operation and water quality happened as a result of this expansion. The upgraded sewage treatment system is designed based on a flow rate of 240 L per day per room for 546 people, for an average daily flow rate of 131 m<sup>3</sup>/day (5.42 cubic metres per hour [m<sup>3</sup>/hour]).

The sewage treatment plant receives two streams of sewage. The first source is domestic sewage, which is fed directly to the fine screening process to remove any fibers or debris that might damage the membranes. The second source is kitchen sewage which is pre-treated in the oil and grease tanks to remove oil and grease prior to being fed into the fine screen.

The STP for the camp facilities is designed to meet appropriate guidelines for wastewater discharge (for example, NWT Water Board 1992). Wastewater System Effluent Regulations (WSER) criteria are not currently applicable to systems located in Nunavut and is unlikely to apply to the Project effluent quality.

Table 3.5 provides the anticipated performance of the system compared to the WSER criteria. Further information on the management of this facility is described in the Whale Tail Sewage Treatment Plant Operation and Maintenance Manual (Agnico Eagle, 2019a).. As stipulated in Part B, Item 17, Agnico Eagle will review the Plans as required by changes in operation and/or technology and modify the Plans accordingly in the form of an addendum to be included in the Annual Report.

**Table 3.5 Effluent Quality and Wastewater Characteristics**

Parameter	Units	Regulatory Limit	Design Value
<b>Wastewater</b>			
• Biochemical Oxygen Demand	mg/L	-	952
• Total Suspended Solids	mg/L	-	300
• Total Kjeldahl Nitrogen	mg/L	-	130
• Ammonia Nitrogen	mg/L	-	130
• Fat, Oil and Grease	mg/L	-	30
• pH	-	-	6 to 9.5
• Water Temperature	°C	-	10 to 25
• Alkalinity	mg/L as CaCO <sub>3</sub>	-	471.1
• Prohibited Chemicals/Compounds	Not present		
• Grinder Pumps	Not present Upstream of MBR		
<b>Effluent</b>			
• pH	-	6-9.5	6.5 to 8.5

• Total Residual Chlorine	mg/L	<0.02	0
---------------------------	------	-------	---

1. Noted values are assumed blended between kitchen and dormitory wastewater after the grease trap.
2. A complete list of prohibited chemicals is included in the membrane maintenance manual.

**3.2 Water Management During Closure**

Mine closure is integral to the mine design and will be modified during operations. Planning for permanent closure is an active and iterative process. The intent of the process is to develop a final closure plan including specific water management components using adaptive management. This begins during the mine design phase and continues through to closure implementation. Adaptive management enables the plan to evolve as new information becomes available through analysis, testing, monitoring, and progressive reclamation. The detailed mine closure and reclamation activities are provided in the Whale Tail Pit Interim Closure and Reclamation Plan (Golder, 2020).

Water management during closure and reclamation will involve actively filling the underground facilities and IVR Pit, and passively allowing the Whale Tail Attenuation Pond and the Whale Tail Pit to flood. The Groundwater Storage Ponds and IVR Attenuation Pond will be emptied at the start of closure and backfilled with NPAG/NML waste rock. The Whale Tail and IVR WRSFs will be progressively covered with NPAG/NML waste rock throughout operations and are expected to be completely covered at the beginning of closure.

Water management during closure and reclamation will involve maintaining contact water management systems on site until monitoring results demonstrate that water quality is acceptable for discharge of all contact water to the environment without further treatment. Once pit lake water quality meets the discharge criteria, the water management systems will be decommissioned to allow the water to naturally flow to the receiving environment. In 2018, a Whale Tail WRSF seepage analysis and hydrodynamic modelling of Mammoth Lake were conducted to address NIRB project certificate Term and Condition no. 6a. The objectives were to assess Mammoth Lake near-field water quality at the WRSF seepage outlet post-closure and to evaluate seasonal water circulation patterns in Mammoth Lake resulting from effluent discharge. This analysis also aimed to predict and evaluate the water quality within Mammoth Lake during operations and post-closure (Golder, 2019c). Results show that no modification to the water management strategy is needed concerning closure activities and sequence.

Runoff from the Whale Tail WRSF and discharge from Whale Tail Lake (North Basin) (IVR runoff flows to Whale Tail Lake (North Basin)) will enter and mix in Mammoth Lake. Concentrations outside the mixing zone of the Whale Tail WRSF contact water plume are predicted to meet receiving water quality criteria. Results of the studies showed that baseline drainage patterns of East Sector needs to be re-established to direct runoff towards the Whale Tail Attenuation Pond, including runoff over the backfilled IVR Attenuation Pond. Runoff from the IVR WRSF and the backfilled Groundwater Storage Ponds needs to be passively directed to the Whale Tail Pit. The IVR Pit walls are composed primarily

of south komatiite and basalt with some north greywacke rock. Based on these predictions, a control mechanism will be required for IVR Pit Walls including re-sloping and cover placement.

The dewatered Whale Tail Pit and IVR Pit area will be filled with a combination of natural runoff and contact water from the entire site (i.e., the Whale Tail and IVR WRSF Contact Water Collection Systems and the Whale Tail and IVR Attenuation Ponds), and water pumped from Whale Tail Lake (South Basin). The runoff and seepage from the Whale Tail WRSF and IVR WRSF will continue to be collected in the designated collection ponds and pumped to Whale Tail Lake (North Basin) during active closure (re-filling). Water will be monitored during flooding and until results demonstrate that water quality conditions from the WRSFs are acceptable for direct discharge. Based on the cover thermal model results, the Whale Tail WRSF and IVR WRSF will be covered with a cover of 4.7 m thick to be constructed with NPAG/NML waste rock. The intent of the cover is to contain the yearly active layer inside the thickness of the cover and to maintain a temperature below 0° Celsius for the underlying rock. The objective of the cover is the control of acid generating reactions and of migration of contaminants by freezing. Consistent with the Approved Project, the segregation of the PAG/NPAG and ML/NML waste rock will occur during the operation of the mine.

The key water management activities during mine closure are summarized in Table 3-6. Appendix B shows the water management flowsheets during mine closure phases.

**Table 3.6 Key Water Management Activities During Mine Closure**

Mine Year	Key Water Management Activities and Sequence
Year 8 (2026)	<ul style="list-style-type: none"> <li>• Dewater the Groundwater Storage Ponds and the IVR Attenuation Pond to the underground mine</li> <li>• Backfill the Groundwater Storage Ponds and the IVR Attenuation Pond with NPAG/NML waste rock</li> <li>• Draw-down of the raised Whale Tail Lake (South Basin) to 153.5 masl, pumping to the underground until refilled and then to the IVR Pit. Lake A55, Lake A65, Lake A62, Lake A63, Lake A18, Pond A-P23, Lake A20, Lake A21, Lake A22, and Lake A45 return to baseline elevations.</li> <li>• Water from Whale Tail Lake (South Basin) ceases flow through Whale Tail Lake Diversion Channel and to Lake A16 (Mammoth Lake)</li> <li>• Decommission IVR Diversion to re-establish baseline drainage patterns of the Northeast Sector catchment towards the IVR Pit</li> <li>• Pump WRSF Pond water to the IVR Pit</li> <li>• Pump Whale Tail Lake (South Basin) to the IVR Pit during summer months to maintain its elevation at 153.5 masl</li> <li>• Re-establish baseline drainage patterns of East Sector runoff towards the Whale Tail Attenuation Pond, including runoff over the backfilled IVR Attenuation Pond</li> <li>• The Whale Tail Attenuation Pond overflows (once full) into the Whale Tail Pit</li> <li>• Passively direct runoff from the IVR WRSF and the backfilled Groundwater Storage Pond to the Whale Tail Pit</li> <li>• Runoff from the backfilled Groundwater Storage Ponds flow to the Whale Tail Pit</li> </ul>

Mine Year	Key Water Management Activities and Sequence
	<ul style="list-style-type: none"> <li>Start of site water quality monitoring of flooding open pit reservoirs</li> </ul>
Year 9 to Year 23 (2027 to 2041)	<ul style="list-style-type: none"> <li>Refilling of the IVR Pit to 149.3 masl (i.e., the spill elevation of the IVR Pit onto the bed of Whale Tail Lake [North Basin]) expected in 2027</li> <li>The IVR Pit reaches the spill elevation to the Whale Tail Pit and begins overflowing to the Whale Tail Pit</li> <li>A sill will be constructed at closure on the upstream of Mammoth Lake to increase the water level by 1 m to 153.5 m.</li> </ul>
Year 24 (2042)	<ul style="list-style-type: none"> <li>The Whale Tail Pit reaches the spill elevation that connects it with the Whale Tail Attenuation Pond and both water bodies fill simultaneously</li> <li>The Whale Tail Pit and the Whale Tail Attenuation Pond reach the spill elevation that connects the Whale Tail Pit with the IVR Pit, and all three reservoirs fill simultaneously to 153.5 masl, forming Whale Tail Lake (North Basin)</li> <li>Once Whale Tail Lake (North Basin) is flooded to 153.5 masl, pumping of the Whale Tail Lake (South Basin) to Whale Tail Lake (North Basin) during summer months will be on-going to maintain the elevation of Whale Tail Lake (South Basin) to 153.5 masl until water quality allows to decommission the dikes and reconnect the North and South Basins of Whale Tail Lake</li> <li>Once Whale Tail Lake (North Basin) is flooded to 153.5 masl, remove STP</li> <li>Once Whale Tail Lake (North Basin) is flooded to 153.5 masl, decommission the Whale Tail WRSF Dike and re-establish natural drainage patterns of the Whale Tail WRSF Sector Lake A16 (Mammoth Lake)</li> <li>Once Whale Tail Lake (North Basin) is flooded to 153.5 masl, create spillway in Mammoth Dike to re-establish baseline flow patterns to Lake A16 (Mammoth Lake)</li> <li>Decommission the Whale Tail Dike, water quality permitting</li> <li>Remove site infrastructure</li> </ul>
Post-Closure (2043+) (triggered when water quality in all three water bodies meets the appropriate water quality criteria)	<ul style="list-style-type: none"> <li>Monitoring</li> </ul>

WRSF = Waste Rock Storage Facility; N/A = not applicable.

### 3.2.1 Flooding Sequence

The flooding sequence will be adapted to meet water quality closure objectives to allow for the reconnection of the lakes. Both the water balance and water quality forecast will be updated during operations and closure phases in order to optimize the flooding sequence.

The Whale Tail Open Pit will be filled with a combination of natural runoff and contact water from the entire site. The Underground mine and the IVR Open Pit will be filled with a combination of natural runoff and contact water from the entire site and water pumped from Whale Tail Lake (South Basin). Flooding will begin following the end of operations.

Beginning in 2026, the water accumulated in Whale Tail Lake (South Basin) over the years of operations will be pumped into the underground mine until it is filled and into the IVR Pit thereafter. Active closure will be consistent with the Approved Project and current Type A Water Licence 2AM-WTP1830. Whale Tail Pit active closure will be followed by passive closure measures until the pits and underground have flooded, Whale Tail Lake and IVR Pit water levels are restored, and runoff from the WRSFs are shown to be suitable for uncontrolled release.

The Whale Tail Pit operations will be closed and reclaimed in a manner consistent with the Approved Project and as required under Project Certificate No. 008 and Type A Water Licence 2AM-WTP1830.

It is anticipated that approximately 72,000,000 m<sup>3</sup> over 16 years from Whale Tail Lake is required to fill the mined-out Whale Tail Pit (i.e., approximately 55,000,000 m<sup>3</sup>), IVR Pit (i.e., approximately 10,000,000 m<sup>3</sup>), underground mine (i.e., approximately 1,000,000 m<sup>3</sup>) and Whale Tail Lake (North Basin) (i.e., approximately 6,000,000 m<sup>3</sup>), including approximately 2,900,000 m<sup>3</sup>/year from Whale Tail Lake (South Basin).

Following the first pumping summer, the water elevation in Whale Tail Lake (South Basin) will be back to the baseline value (153.5 masl) and no outlets will be available for this basin as the Whale Tail Lake (South Basin). The elevation of the Mammoth sill will be 153.5 masl. The Diversion Channel inlet is at the elevation 155.3 masl and the Whale Tail Dike is maintained in place. Refilling of the IVR Pit to 149.3 masl (i.e., the spill elevation of the IVR Pit onto Whale Tail Lake (North Basin) is expected in 2027. Refilling of Whale Tail Pit to 146.3 masl (i.e., the spill elevation of the Whale Tail Pit onto the bed of Whale Tail Lake (North Basin) is expected in 2039.

### **3.2.2 Contact Water Collection System**

The contact water collection system will remain in place to collect surface runoff water and seepage from the mine site until the open pits are flooded. During this period, the Industrial Sector and the Whale Tail Camp will be reclaimed, and the non-essential site infrastructure will be removed. Thereafter, water in these sectors will no longer be collected and will contribute to the reestablishment of the natural elevation of Whale Tail Lake (North Basin). The Mammoth Dike and Whale Tail Dike will remain in place until pit lake water quality meets receiving environment water quality objectives. If this occurs after full flooding as is predicted at this time, the pit lake water elevation will be maintained at 153.5 masl by pumping from Whale Tail (South Basin) to the North Basin, and through controlled discharge from Whale Tail (North Basin) to Mammoth Lake over the Mammoth sill.

In the Whale Tail WRSF Sector, the contact water collection system will remain in place. Dikes will not be reconnected until the water quality in the flooded area meets Closure water quality objectives. Contingency for water treatment if required in closure is also accounted for in the closure plan.

In closure, water from the Whale Tail WRSF Contact Water Collection System is used to actively flood IVR Pit, and the IVR WRSF water is directed to Whale Tail Pit. In post-closure, water from the Whale Tail WRSF Contact Water Collection System is allowed to flow passively to Mammoth Lake as baseline drainage patterns are re-established. Lower volumes and chemical loading of water originating from either of the WRSFs would improve water quality throughout closure in the Whale Tail and IVR Pits, and in Mammoth Lake in post-closure.

Dike decommissioning will involve the removal (breach) of a portion of the dike to original ground levels whenever possible. Consideration will be given to breach staging, with the above water portions of the dike/berm in the breach area removed during winter periods, when there will be little surface water flow, thereby minimizing the potential release of sediments to the neighbouring waterbodies. The remainder of the breach would be completed during the open water season following freshet to allow for the deployment of turbidity curtains to control potential releases of sediment.

For water collection and management systems closure the infrastructure will be re-contoured and/or surface treated according to site-specific conditions to minimize wind-blown dust and erosion from surface runoff, if required. This closure activity is intended to enhance site area development for re-colonization by native plants and wildlife habitat.

### **3.2.3 Post-Closure Modeling Results Summary**

Following refilling of Whale Tail Lake (North Basin) to 153.5 masl (i.e., to overtop the Mammoth Lake sill), and once the pit lake water quality is acceptable (full flooding predicted to occur in 2042; adequate water quality in 2042; Golder 2019c), the Whale Tail Dike, Mammoth Dike, and the Whale Tail WRSF Dike are decommissioned. Whale Tail Lake (North Basin) and Whale Tail Lake (South Basin) form Whale Tail Lake with a water surface area of 2.34 km<sup>2</sup>, or a 41% increase from baseline, which flows to Lake A16 (Mammoth Lake) over the Mammoth Lake Dike via spillway. Runoff from the Whale Tail WRSF Contact Water Collection System area flows to Lake A16 (Mammoth Lake).

The reflooding strategy will be adapted during closure based on future water quality predictions validated with site monitoring data. The objective will be for pit lake water to meet quality objectives concurrently with completed reflooding such that lake reconnection can happen as soon as possible after thereafter.

Steady-state untreated WRSF contact water released is predicted to meet SSWQO for arsenic at the edge of the mixing zone in the long-term, under the anticipated cover performance scenario (from the 4.7 meters cover of low arsenic leaching waste rock).

The mixing zone in the Lake is predicted to range from 5 meters (under calm conditions in July when 6% of the seasonal seepage flow occurs), to 60 meters (under medium current conditions in June when 65% of the seasonal flow is predicted to occur at a more dilute arsenic concentration) from the entry point of this seepage into the Lake and along the plume centre line.

Other inflows to Mammoth Lake include natural runoff and overflow from Whale Tail Lake; both are predicted to meet SSWQO as described in FEIS Appendix 6H (Agnico Eagle, 2016).

Mammoth Lake is sensitive to cover material seepage quality, which is in turn sensitive to cover composition and WRSF pile contact water volume. Observational data at the Meadowbank WRSF suggests that pile contact water volumes are substantially lower than originally predicted (Portage is 20 to 40% lower, Vault WRSF contact water is minimal compared to 178,000m<sup>3</sup> predicted at maximum footprint year) using similar modelling assumptions. Recent modelling results of the WRSF landform reflect a significant reduction in the volume of seepage from the WRSF and conservative chemical load estimate to Mammoth Lake which will be verified with monitoring. As per Type A Water Licence 2AM-WTP1830 Part E, conditions 5 and 6, Agnico Eagle completes a site wide water balance and pit water quality model update for the Whale Tail Pit Site as part of the annual water management plan.

### 3.3 Water Balance

As per the Type A Water Licence 2AM-WTP1830, Part E, Item 5, a Project water balance will be updated and presented on an annual basis, integrated into the water management plan update. The developed water balance will assist in evaluating future water management infrastructure, including under closure conditions (Whale Tail Interim Closure and Reclamation Plan).

The water balance was computed on a monthly time step based on mean annual climate conditions (Section 2.1.1). The water management flow sheets are presented in Appendix B, and the full water balance report is presented in Appendix C (Whale Tail Pit – Expansion Project Mean Annual Water Balance (Golder 2021)).

### 3.4 Water Quality Forecast

Water quality forecast reports will be revisited on an annual basis until mine closure, as per the Water License part E item 8. The purposes of the report are to identify, through a mass balance approach, the contaminants of concern during the pit flooding process and WRSF contact water mixing into Mammoth Lake post-closure, and determine if water treatment will be required on site for closure activities when comparing the final contaminant levels to the CCME guidelines and/or site specific criteria for parameters that are not included in the CCME Guidelines.

In the 2021 report (Golder 2021a), Golder presents that water quality indicators remain mostly stable from 2021 through operations. Because of the development of differing seasonal trends in the Whale Tail WRSP pond, analysis of monitoring data from the Whale Tail WRSF in future years will provide support for the calibration. In the Whale Tail Attenuation Pond, modelled constituents that showed

concentrations consistently above their respective EQCs were total aluminum, iron, and chromium. Total phosphorus, arsenic, mercury, cadmium, copper, nickel, lead, zinc, and ammonia remained below their respective EQCs. The IVR Attenuation Pond was included for the first time in the water quality model. For this pond, arsenic treatment is expected to be required over the entire operation period. Predicted concentrations for phosphorus remain below the site EQC for the duration of operations, though daily variability in the monitoring data shows concentrations approaching the EQC and supports the continuation of treatment prior to discharge. Modelled constituents that showed concentrations consistently above their respective EQCs were total aluminum and iron. Total mercury, cadmium, chromium, copper, nickel, lead, zinc, and ammonia remained below their respective EQCs. It is anticipated that the IVR Attenuation Pond will require further calibration in future years as it becomes operational and monitoring data are available.

At closure and post-closure, flooded pit water quality is predicted to meet receiving water quality criteria when flooding is complete, allowing reconnection with the downstream receiving environment. Arsenic release from the submerged Whale Tail Pit walls is anticipated once pit-flooding commences but is expected to be a relatively short-lived source (a few years) to the flooded pit lake.

### **3.5 Adaptive Management**

Adaptive management will be achieved through performance monitoring and management actions that will be implemented, should they be triggered. Action level responses taken during the year will be documented in Agnico Eagle's annual report submitted to the NWB. The Whale Tail Pit Expansion Project – Adaptive Management Plan (Agnico Eagle, 2020c) includes the specific adaptive management strategies that will be implemented in the WRSF to meet water quality objectives, and chemical and physical stability of the WRSFs during operations, closure, and post-closure phases. The Adaptive Management Plan is still under approval by the Nunavut Water Board but once approved this plan will fully cover the adaptive management strategy.

Water Balance Results – Flow Diagrams

## 1.0 INTRODUCTION

Agnico Eagle Mines Limited: Meadowbank Division (Agnico Eagle) is developing the Whale Tail and IVR pits and underground operations on the Amaruq property (the Project), in continuation of mine operations and milling of the Meadowbank Mine. The Amaruq Exploration property is a 408 km<sup>2</sup> site located on Inuit Owned Land approximately 150 km north of the hamlet of Baker Lake and approximately 50 km north of the Meadowbank Mine in the Kivalliq region of Nunavut.

The Project supports the mining of approximately 23.6 million tonnes of ore from the operations, processed over the mine life. As a part of its commitment under the Type A Water Licence 2AM-WTP1830, Part E, Item 6, Agnico Eagle has agreed to submit an updated water management plan on an annual basis to the Board for review following the commencement of operations.

This report presents the water balance component of the 2020 Annual Report, including a description of water management activities and the mean annual water balance for the Project, from operations to post-closure, starting in 2020. The water balance includes data collected at the site in 2020. It is limited to catchments of the Project footprint and does not address the receiving environment within and downstream of the effluent discharge point.

Water quality predictions corresponding to the Project's mean annual water balance are presented under a separate cover (Golder 2021).

## 2.0 WATER MANAGEMENT SUMMARY

The Project consists of mining from the Whale Tail and IVR Pits and underground operations. The 2020 site layout is shown in Figure 1, with the key water management features labelled. The ultimate layout is provided in the water management plan (Agnico Eagle 2021). The main objectives pertaining to water management are to minimize: the quantity of contact water that must be managed; and potential impacts on the receiving environment. The water management plan was developed using the following principles (Agnico Eagle 2016):

- Keep the different water types separated to the extent feasible;
- Control and minimize contact water through diversion and containment;
- Minimize freshwater consumption by recycling and reusing the contact and process water wherever feasible; and
- Meet discharge criteria before any site contact water is released to the downstream environment.

Non-contact surface water is diverted and discharged directly into the environment without treatment.

Runoff from the surface facilities is collected in sumps or ponds around the Project and pumped to a central location before being treated and discharged to either Whale Tail Lake (South Basin) or Mammoth Lake.

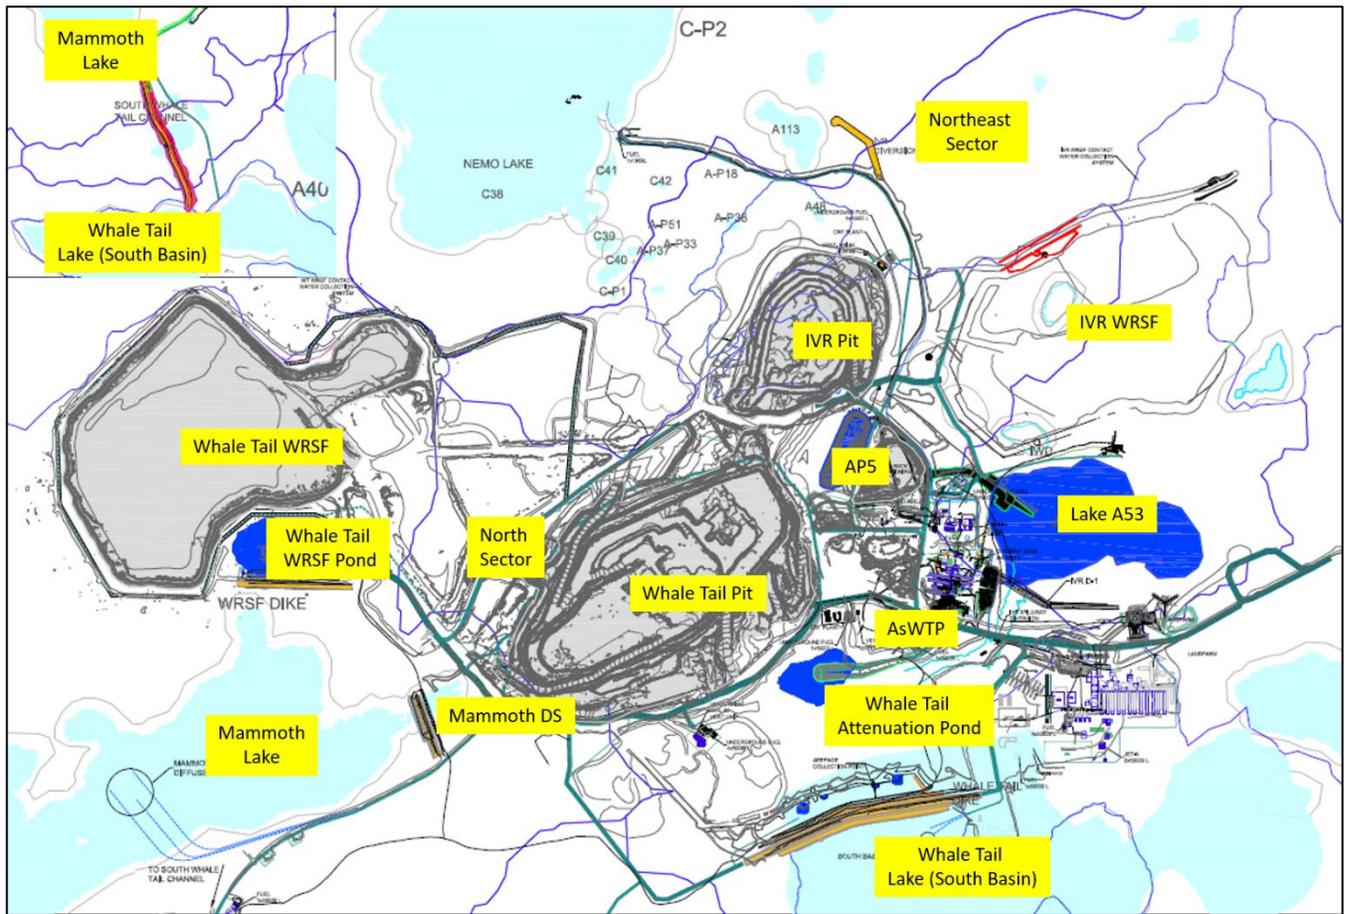

Figure 1: Current Water Management Facilities – 2020

## 2.1 2020 Winter Water Management

The mining of Whale Tail Pit required the dewatering of Whale Tail Lake (North Basin). Dewatering of the basin was completed by May 15, 2020. Whale Tail Dike (WTD) seepage water reporting to Whale Tail Lake (North Basin) was discharged back to Whale Tail Lake (South Basin) where it accumulated below the diversion invert to Mammoth lake. Prior to dewatering, mining occurred in the portions of the Whale Tail Pit that are above Whale Tail Lake (North Basin). The eastern portion is referred to as Quarry 1, and the western area as Whale Tail (Starter) Pit. During the dewatering period, Quarry 1 was the established attenuation pond on site. Its collected water was pumped to Mammoth Lake either directly or via the Arsenic water treatment plant (AsWTP) depending on the water quality relative to the discharge criteria.

The water management activities for the winter of 2020 are illustrated in the form of a flow diagram in Figure 2.

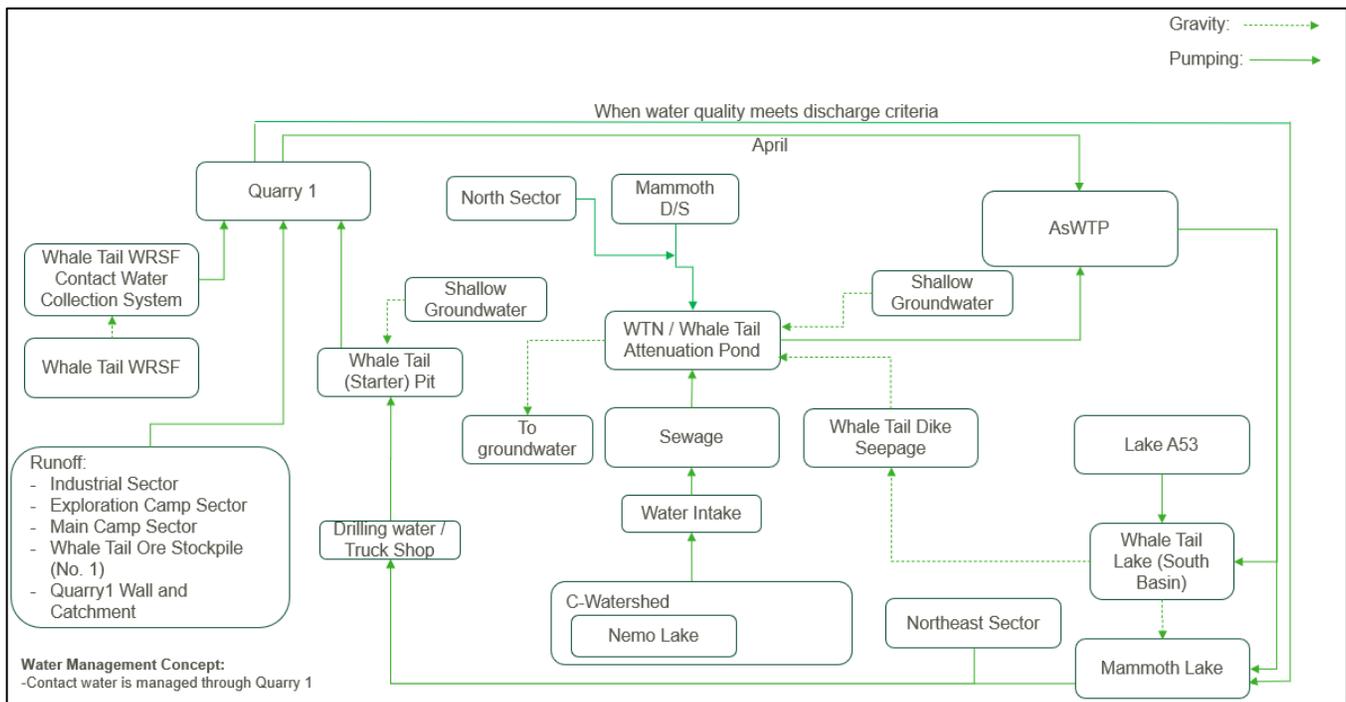

Figure 2: Conceptual Flow Diagram: Winter 2020

## 2.2 June 2020– June 2021 Water Management

Starting in the spring of 2020, Quarry 1 and the Whale Tail (Starter) Pit merged to form the Whale Tail Pit. The Whale Tail Attenuation Pond became the established attenuation pond, collecting all contact water on site. Water from the Whale Tail Attenuation Pond was discharged to either Mammoth Lake or Whale Tail Lake (South Basin) via the AsWTP, depending on water quality in the receiver. For 4 days in June, water was also temporarily pumped to AP5 before being pumped back to the Whale Tail Attenuation Pond in August for eventual discharge from site.

Whale Tail Attenuation Pond will be the established attenuation pond until Freshet 2021, when the IVR Attenuation Pond comes online. At that point, the IVR Attenuation Pond will be the preferred discharge location; the Whale Tail Attenuation Pond will remain available if / when required.

The water management activities from June 2020 to June 2021 are illustrated in the form of a flow diagram in Figure 3.

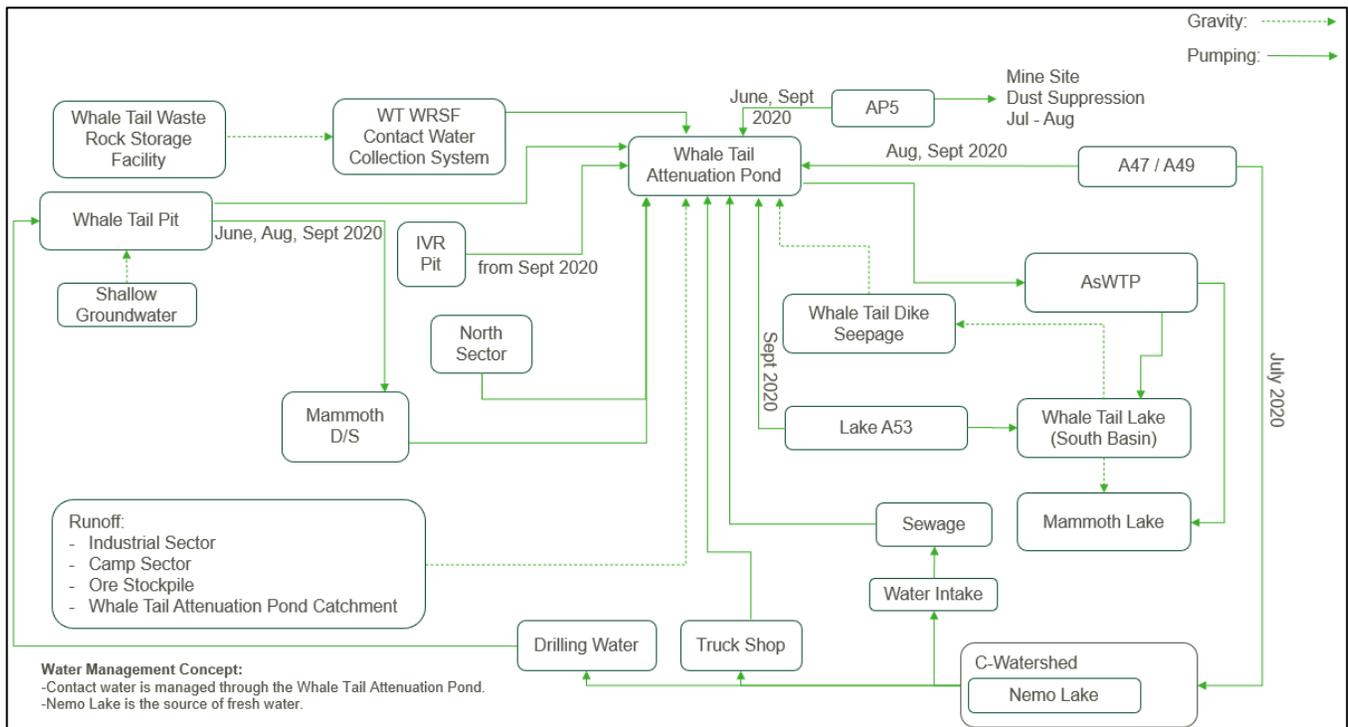

Figure 3: Conceptual Flow Diagram: June 2020 – June 2021

### 2.3 July 2021 to the End of Operations Water Management

Starting with the 2021 spring melt, all site contact water will report to the IVR Attenuation Pond (former Lake A53, which will discharge - via the AsWTP - to Whale Tail Lake (South Basin) in the winter and Mammoth Lake in the summer. At that point, the Whale Tail Attenuation Pond will only collect WTD seepage, Camp Biodisk flows and runoff.

The planned water management activities for the remainder of operations are illustrated in the form of a flow diagram in Figure 4.

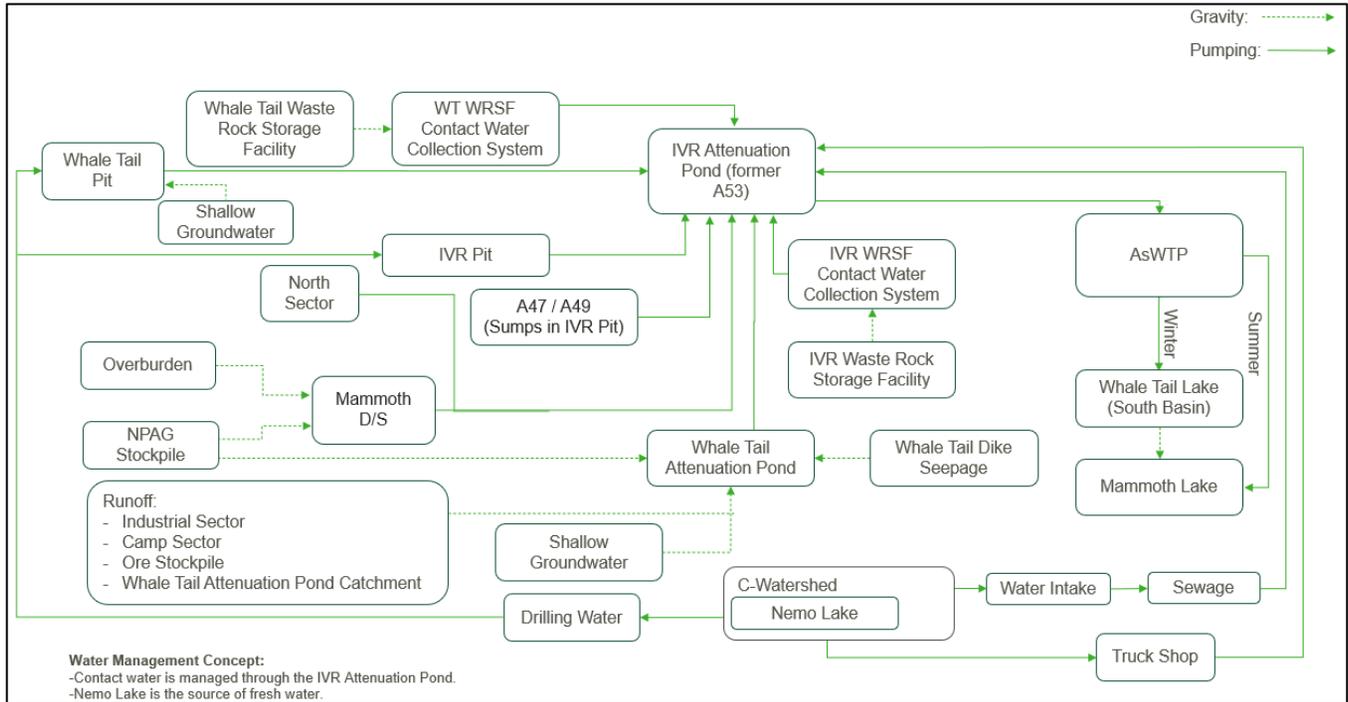

Figure 4: Conceptual Flow Diagram: July 2021 – End of Operations (December 2025)

## 2.4 Closure Water Management

At closure, the pits and Attenuation Ponds will be allowed to refill. To expedite the filling process, the runoff from the managed catchments will be conveyed to IVR Pit, and to the rest of Whale Tail Lake (North Basin) once the IVR Pit is refilled. As part of this process, Whale Tail Lake (South Basin) will be drawn down. As part of the Whale Tail Project Fisheries Offsetting, at closure, aquatic habitat at the Project will be created by maintaining a higher water level than the baseline level in Whale Tail Lake (Agnico Eagle 2016). A sill will be constructed at the Mammoth Dike to raise water levels in Whale Tail Lake to a surface elevation of 153.5 masl (i.e., 1 metre over the baseline elevation).

The water management activities for the closure period are illustrated in the form of a flow diagram in Figure 5.

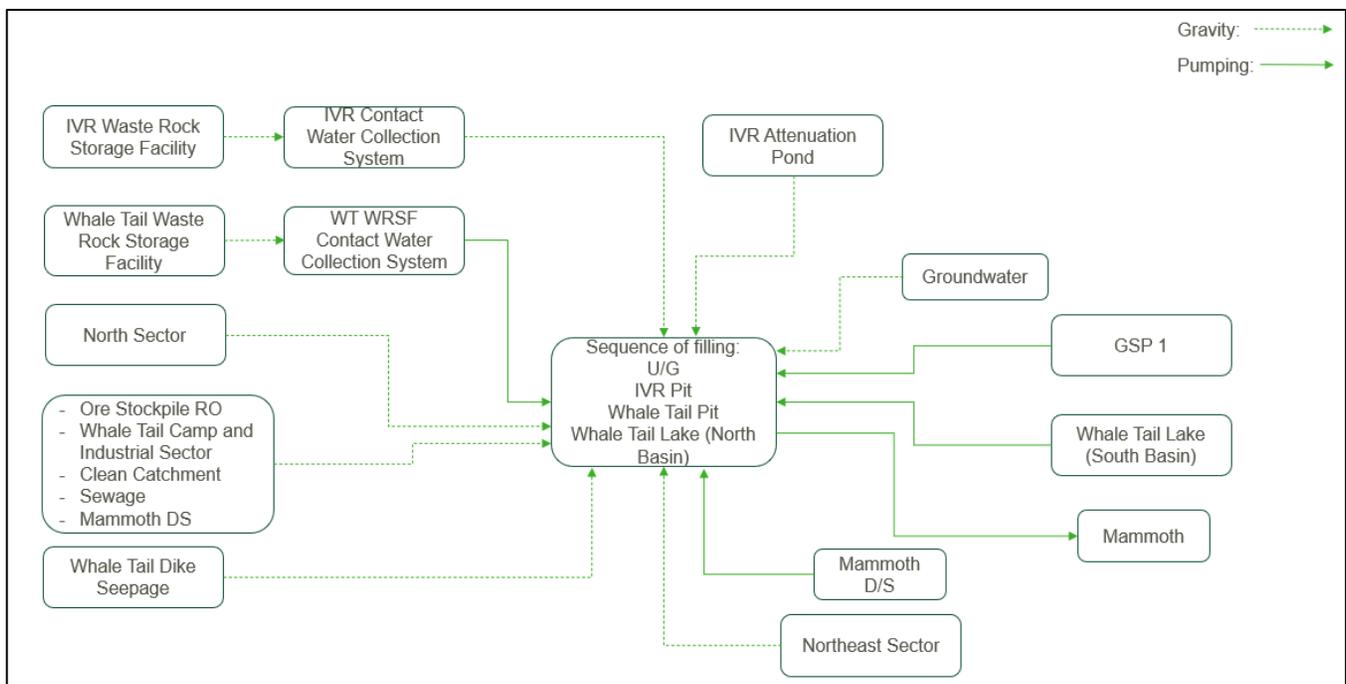

Figure 5: Conceptual Flow Diagram for Closure

### 3.0 WATER BALANCE BASIS

The inputs and assumptions used in the water balance have been summarized in the Project design document presented in Appendix A. These include site climate inputs, mine plan, consumptive flows and hydrogeological inputs and assumptions. Reported data were used instead of design values in 2020.

### 4.0 MEAN ANNUAL WATER BALANCE RESULTS

A summary of the managed catchments, water balance inputs and graphical results is presented below. The monthly water balance results are presented in tabular and schematic format in Appendices B and C, respectively. Results are provided for the period of 2020 to post-closure.

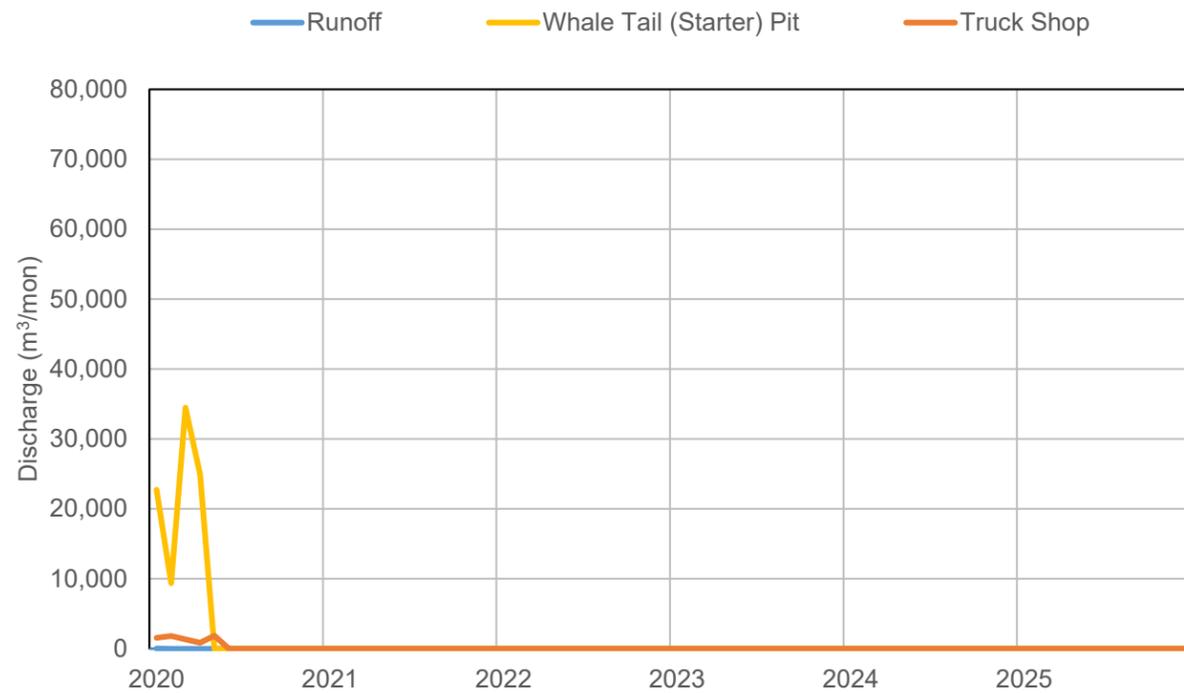

#### 4.1 Quarry 1

Prior to the dewatering of Whale Tail Lake (North Basin), mining occurred in Quarry 1 and the Whale Tail (Starter) Pit. The Whale Tail Pit and Quarry 1 merged and are modelled as the Whale Tail Pit after June 2020. Once mining was completed in Quarry 1, Quarry 1 acted as the site attenuation pond until the Whale Tail Attenuation Pond came online in June 2020. The quarry received inflows from the Whale Tail Waste Rock Storage Facility (WRSF), the Whale Tail Pit, the Industrial and Camp sectors as well as drilling water and flows from the truck shop. In 2020, water from Quarry 1 was discharged to Mammoth Lake either directly (if water quality met discharge criteria) or via the AsWTP.

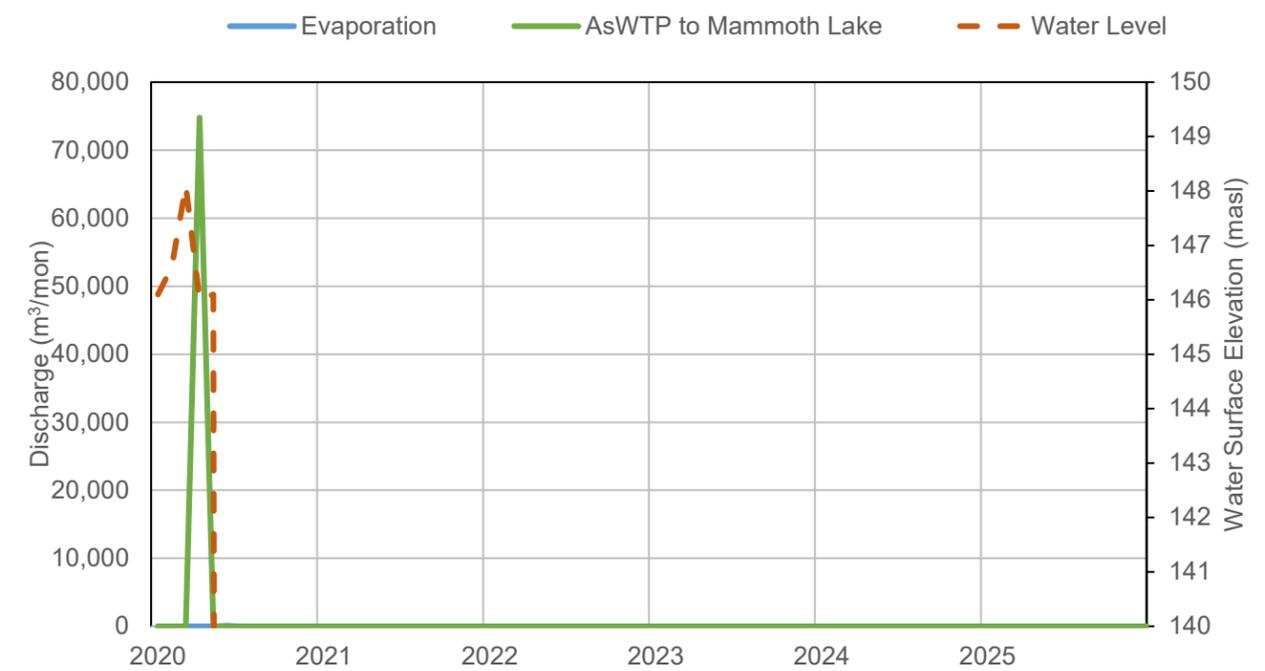

Inflows and outflows are summarized in Table 1, Figure 6 and Figure 7, and presented in tabular form in Appendix B.

**Figure 7: Outflows from Quarry 1 (Operations)**

## 4.2 AP5 / GSP1

AP5/GSP1 is located just northeast of, and drains naturally to, Whale Tail Lake. The pond was excavated and pumped dry prior to 2018 to permanently increase capacity to manage runoff. The pond receives runoff from its watershed, which includes the underground waste rock storage facility and ore stockpiles and the underground portal. Excess water from the Whale Tail Attenuation Pond was also temporarily pumped to AP5 in June 2020. In September 2020, AP5 was pumped dry and no longer received contact water to provide capacity in the event that saline water storage from the underground workings was required. At this point, AP5 was renamed Groundwater Storage Pond 1 (GSP1). Water reporting to GSP1 will accumulate. If GSP1 reaches capacity, overflow will be discharged to available underground stopes where mining has been completed. At closure, GSP1 will be pumped to the underground and GSP1 will be backfilled.

Inflows and outflows for AP5 / GSP1 are summarized in Table 2, Figure 8 to Figure 11, and presented in tabular form in Appendix B.

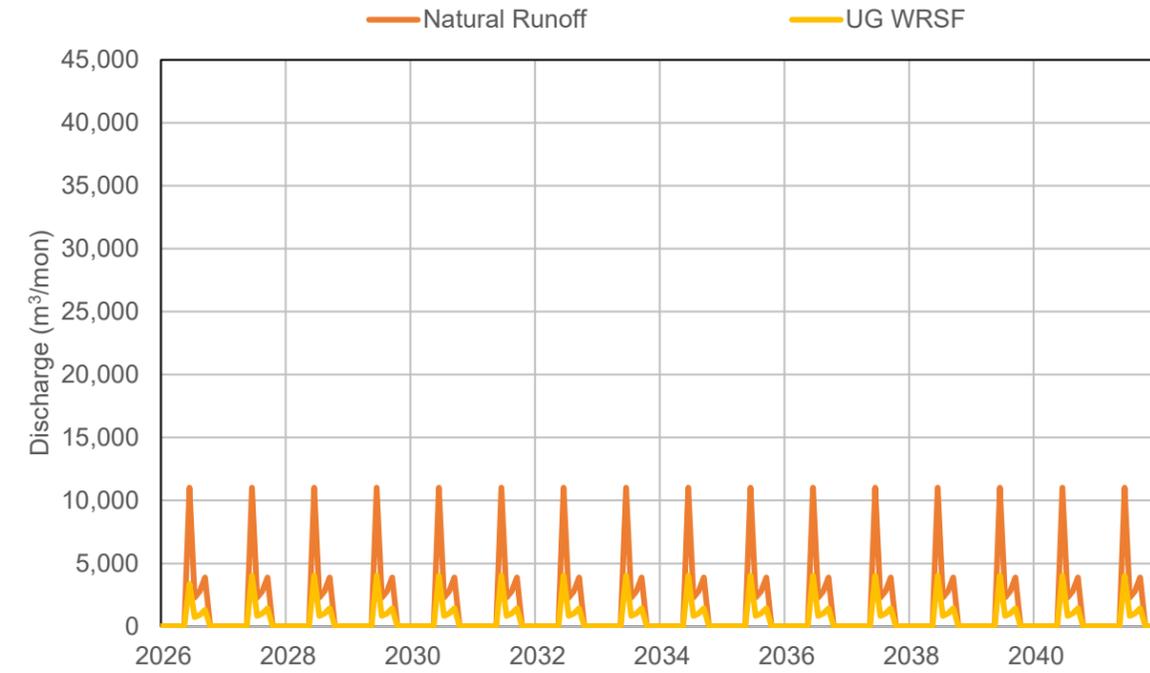

Figure 9: Inflow from AP5 / GSP1 (Closure)

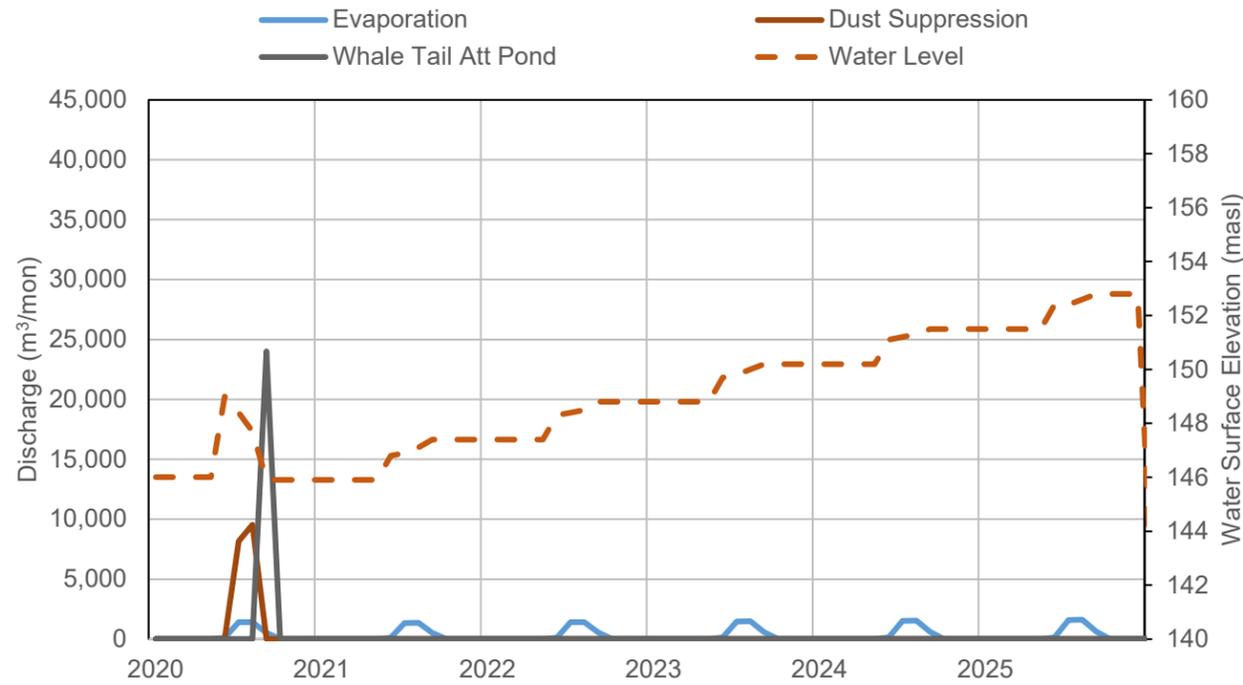

Figure 10: Outflow to AP5 / GSP1 (Operations)

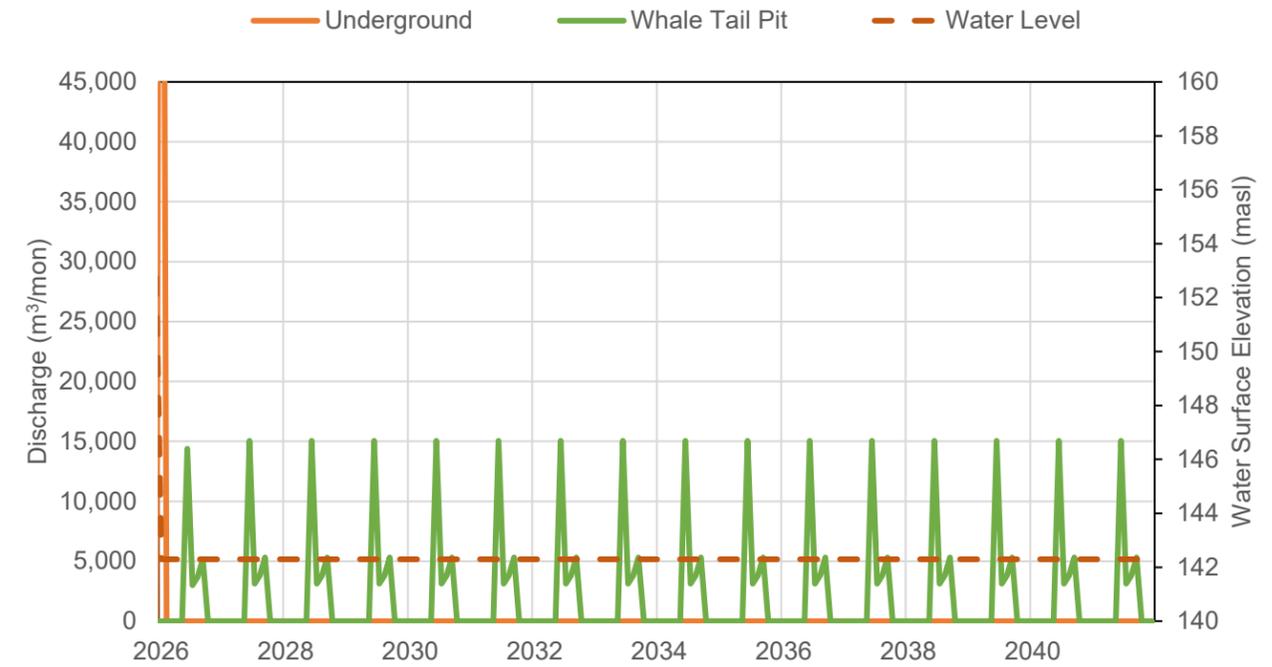

Figure 11: Outflows from AP5 / GSP1 (Closure)

### 4.3 Northeast Sector

The Northeast Sector consists of the catchment draining into Lakes A49 and A47. Prior to the operations of IVR pit, this catchment was impounded by the Northeast Dike (operational in January 2019) and diverted to the C-watershed. By September 2020, the Northeast Dike was decommissioned and Phase 1 of the IVR Pit was operational. At this point, Lakes A49 and A47 became sumps within the IVR Pit footprint; their inflows were pumped to the Whale Tail Attenuation Pond. This is expected to continue until the expansion of the IVR pit to its ultimate footprint, at which time Lakes A49 and A47 will cease to exist and their upstream catchment (Northeast Channel [NE Channel]) will be diverted north towards the C-watershed.

Inflows and outflows are summarized in Table 3 and Figure 12 to Figure 15, and presented in tabular form in Appendix B.

**Table 3: Water Balance Flow Components (Northeast Sector)**

## 4.4 Whale Tail Waste Rock Storage Facility Contact Water Collection System

The catchment of the Whale Tail WRSF Contact Water Collection System is located in the northern headwaters of the Mammoth Lake catchment. Its runoff drained naturally to Mammoth Lake until Licence A was approved in July 2018. Since then, runoff reporting to the collection system was collected in the Whale Tail WRSF Pond and pumped to the Whale Tail Attenuation Pond. The current plan is to continue pumping to Whale Tail Attenuation Pond until the IVR Attenuation Pond comes online in 2021. Runoff from the Whale Tail WRSF Pond will then be discharged to the IVR Attenuation Pond until closure.

Due to seepage through the Whale Tail WRSF Dike in 2019, since September 2019, no water has been accumulating in the Whale Tail WRSF Pond. All runoff reporting to the Whale Tail WRSF Pond is pumped directly to the active attenuation pond (i.e., either the Whale Tail Attenuation Pond or the IVR Attenuation Pond).

At closure, runoff will be pumped to the IVR Pit to expedite refilling of the pits and Whale Tail Lake (North Basin). Natural drainage patterns will be re-established at Post-Closure if water quality criteria are met (i.e., the assumed scenario in this water balance). The Whale Tail WRSF has a drainage area of 1.09 km<sup>2</sup>.

Inflows and outflows are summarized in Table 4 and Figure 16 to Figure 19, and presented in tabular form in Appendix B.

**Table 4: Water Balance Flow Components (Whale Tail WRSF Contact Water Collection System)**

## 4.5 North Sector

The North Sector consists of the northwest catchment area of Whale Tail Lake, just north of its natural lake outlet. The North Sector collection area became operational once Whale Tail Lake (North Basin) was dewatered and is intended to collect water draining north of Whale Tail Pit. The water is then pumped to the depression located upstream of Whale Tail Pit, downstream of Mammoth Dike (i.e., Mammoth Downstream [DS]). The North Sector collection area remains operational until closure when it is decommissioned and its natural drainage patterns towards Whale Tail Lake (North Basin) are re-established. The North Sector collection area has a drainage area of 0.243 km<sup>2</sup>.

Inflows and outflows are summarized in Table 5 and Figure 20 to Figure 23. They are also presented in tabular form in Appendix B.

## 4.6 Whale Tail Pit

Prior to the dewatering of the Whale Tail Lake (North Basin), the Whale Tail Pit had a baseline drainage area of 0.13 km<sup>2</sup>. This increased to 1.17 km<sup>2</sup> once the pit merged with Quarry 1 in June 2020. At closure, natural drainage patterns surrounding the Whale Tail Pit will be re-established to expedite its refilling. The drainage area of the Whale Tail Pit will increase to 29.6 km<sup>2</sup> which includes the sum of the natural drainage area of Whale Tail Lake and of the Whale Tail WRSF (whose flows will be pumped to IVR Pit).

At closure, Whale Tail Pit will be allowed to refill with runoff from its natural catchment and overflow from IVR Pit once it is filled. The Whale Tail Pit is expected to be refilled to 146.3 masl (i.e., the bed elevation of Whale Tail Lake at Whale Tail Pit) by 2039. At that point, it will become part of Whale Tail Lake (North Basin) (Section 4.8).

Inflows and outflows are summarized in Table 6 and Figure 24 to Figure 27. They are also presented in tabular form in Appendix B.

## 4.7 Mammoth Downstream

Mammoth Downstream (DS) is located in the area between Whale Tail Pit and the Mammoth Dike. It collects runoff from its natural catchment, including runoff from the non-potentially acid generating rock (NPAG) stockpile, as well as flows from the North Sector (which actually discharges to the pipeline downstream of Mammoth DS). Its inflows are then pumped to the operational attenuation pond.

At closure, runoff to Mammoth DS will be allowed to overflow to Whale Tail Pit and Whale Tail Lake (North Basin).

Inflows and outflows are summarized in Table 7 and Figure 28 to Figure 31. They are also presented in tabular form in Appendix B.

## 4.8 Whale Tail Lake (North Basin) / Whale Tail Attenuation Pond

The Whale Tail Attenuation Pond is located just south of the Whale Tail Pit. It became operational once Whale Tail Lake (North Basin) was dewatered mid-May 2020.

Prior to mid-May 2020, site contact water (with the exception of flow from the camp biodisk) was managed within Quarry 1; the Whale Tail Lake (North Basin) only received camp biodisk flows and naturally draining runoff (including runoff from the Lake A53 watershed) and seepage through the Whale Tail Dike. During this time, water collected in the Whale Tail Lake (North Basin) was discharged to Whale Tail Lake (South Basin) and Mammoth Lake via the AsWTP.

After mid-May 2020, all site contact water was managed in the Whale Tail Attenuation Pond and discharged to either Whale Tail Lake (South Basin) or Mammoth Lake, via the AsWTP. This will continue until June 2021, when the IVR Attenuation Pond becomes operational until closure. At that time, the contact water collected in the Whale Tail Attenuation Pond will be discharged to the IVR Attenuation Pond.

At closure, the Whale Tail Attenuation Pond will become part of Whale Tail Lake (North Basin) once more upon the filling of the Whale Tail and IVR Pits. As part of the Project's Fisheries Offsetting Plan, the final elevation of Whale Tail Lake (North Basin) will be 153.5 masl. This level will be maintained by the Mammoth Lake sill constructed at the Mammoth Dike at closure. The Whale Tail Dike will remain in place until pit lake water meets quality objectives.

Post-closure will be initiated in 2042 once the final water level is reached, and water quality is acceptable. At that time, drainage patterns will then be re-established towards Mammoth Lake (i.e., water overflows the Mammoth Lake sill) and the Whale Tail Dike will be decommissioned, reconnecting the North and South basins of Whale Tail Lake.

Whale Tail Lake (North Basin) has a baseline catchment area of 28.6 km<sup>2</sup>. This catchment area was reduced to 28.4 km<sup>2</sup> in 2017 from the isolation of the Underground Mine and related water management systems. It was further reduced to 6.12 km<sup>2</sup> with the construction of Whale Tail Dike in 2018. In 2019, the construction of the Northeast Dike and the pumping of the Lake A53 watershed runoff to Whale Tail Lake (South Basin) further reduced the catchment area to 3.05 km<sup>2</sup>. At post-closure, the natural drainage will be restored, returning to baseline conditions.

Inflows and outflows are summarized in Table 8 and Figure 32 to Figure 35. They are also presented in tabular form in Appendix B. Whale Tail Lake (North Basin) is expected to reach the elevation of 153.5 masl by 2042.

## 4.9 IVR Pit

The IVR Pit is located just north of Whale Tail Lake, within the Northeast Sector. The IVR Pit was initiated in September 2020. During Phase 1 of the IVR Pit, runoff from the Northeast Sector reports to Sump A47 (i.e., a sump within the pit footprint) and is pumped to the active attenuation pond (i.e., either the Whale Tail Attenuation Pond or the IVR Attenuation Pond). With the expansion of the pit footprint, runoff from the upstream portion of the Northeast sector will be diverted to the C-watershed. The IVR Pit's operational runoff is conveyed to the active attenuation pond.

The IVR Pit catchment has a drainage area of 1.18 km<sup>2</sup> until closure. At closure, natural drainage patterns surrounding the IVR Pit will be mostly re-established, including the Northeast Sector watershed. Runoff from the Whale Tail Lake (South Basin), the GSP-1 watershed area, the Underground Mine watershed area and the Whale Tail WRSF Contact Water Collection System will be pumped to the IVR Pit to expedite its refilling. The drainage area of the IVR Pit Tail Pit will increase to 25.4 km<sup>2</sup> which includes the sum of the natural drainage area of Whale Tail Lake (South Basin) and of the Whale Tail WRSF.

Inflows and outflows are summarized in Table 9 and Figure 36 to Figure 39. They are also presented in tabular form in Appendix B.

## 4.10 IVR Waste Rock Storage Facility

The IVR WSRF Contact Water Collection System became operational once the IVR Pit was initiated. Prior to its operation, the natural catchment formed a portion of the Northeast Sector. Runoff from the IVR WSRF is captured by perimeter ditches and conveyed to the IVR WSRF Contact Water Collection System prior to being pumped to the active attenuation pond (i.e., either the Whale Tail Attenuation Pond or the IVR Attenuation Pond). At closure, the runoff from this area will be diverted to Whale Tail Pit.

Inflows and outflows are summarized in Table 10 and Figure 40 to Figure 43. They are also presented in tabular form in Appendix B.

## 4.11 Lake A53 / IVR Attenuation Pond

The Lake A53 catchment, is located east of Whale Tail Lake. The catchment remains at baseline conditions until the freshet of 2021, when it becomes the IVR Attenuation Pond following fishout, the construction of the IVR Attenuation Pond Dike, and dewatering of Lake A53. Its outlet drains naturally to Whale Tail Lake (North Basin); in 2020, its flow was diverted to Whale Tail Lake (South Basin). The IVR Attenuation Pond is intended to manage all contact water from 2021 to closure while discharging through the AsWTP during open water conditions. At closure, it will be drawn down by pumping to the Underground Mine, backfilled with NML/NPAG waste rock to decrease its storage to zero and its natural drainage patterns will be re-established towards Whale Tail Lake (North Basin) via the Whale Tail Attenuation Pond.

The IVR Attenuation Pond has a drainage area of 1.32 km<sup>2</sup> at baseline. Its local drainage area diminishes with the increasing IVR WRSF footprint. Contributing catchments include those from the Whale Tail WRSF Contact Water Collection System, the North Sump, the Whale Tail Attenuation Pond, the Whale Tail Pit, the IVR Pit and the IVR WRSF Contact Water Collection System resulting in a total drainage area of 6.48 km<sup>2</sup> during operations. At closure, its drainage area consists of its local drainage area of 0.86 km<sup>2</sup>.

Inflows and outflows are summarized in Table 11 and Figure 44 to Figure 47. They are also presented in tabular form in Appendix B.

## 4.12 Whale Tail Lake (South Basin)

Whale Tail Lake (South Basin) is located south of, and adjacent to, the proposed Whale Tail Dike. Whale Tail Lake (South Basin) was connected to Whale Tail Lake (North Basin) until the construction of the Whale Tail Dike in June 2018. Dewatering of Whale Tail Lake (North Basin) resulted in the flooding of Whale Tail Lake (South Basin) (to an elevation of 156 masl) and overflow of Whale Tail Lake (South Basin) into the Mammoth Lake watershed via an engineered channel during operations.

At the end of operations and into closure, the water level in the South Basin will be lowered permanently to 153.5 masl (i.e., one metre above baseline level) by pumping the flooded volume into the IVR Pit. This water level will be maintained by pumping from Whale Tail Lake (South Basin) into the IVR Pit during closure. Post-closure, the Whale Tail Dike will be decommissioned to re-establish natural drainage patterns in Whale Tail Lake. Whale Tail Lake then flows to Mammoth Lake via the Mammoth sill.

The baseline drainage area of Whale Tail Lake (South Basin), 22.3 km<sup>2</sup> is augmented during the dewatering of Whale Tail Lake (North Basin) in 2019 and by the routing of the Lake A53 Sector runoff to Whale Tail Lake (South Basin) (by pumping) from 2019 to closure.

Inflows and outflows are summarized in Table 12 and Figure 48 to Figure 51. They are also presented in tabular form in Appendix B.

## 4.14 Closure: Flooding of Open Pits and Refilling of Whale Tail Lake (North Basin)

Mine closure will be initiated after cessation of mining activities, in January 2026, until water levels in Whale Tail Lake (North Basin) reach a water surface elevation of 153.5 masl (i.e., 1 metre over the baseline elevation). This water level will be maintained through the construction of a sill at the Mammoth Dike to promote aquatic habitat in the Project site post operations. The water management plan for the closure period is presented conceptually in Figure 5.

The refilling duration of Whale Tail Lake (North Basin) was estimated using the mean annual water balance based on the following assumptions:

- The Whale Tail Pit, IVR Pit, and Underground Mine are not hydraulically connected below the surface during the refilling period.
- Refilling of mining development is prioritized as follows:
  - Underground Mine;
  - IVR Pit; and
  - Whale Tail Pit.
- The Underground Mine is refilled by local catchment runoff, drawdown of GSP 1, IVR Attenuation Pond and partial drawdown of Whale Tail Lake (South Basin) to complete its flooding.
- The IVR Pit is refilled by local catchment runoff, runoff collected in the Whale Tail WRSF Contact Water Collection System, partial drawdown of Whale Tail Lake (South Basin), and diversion of runoff from Whale Tail Lake (South Basin) to maintain its closure water surface elevation (i.e., 153.5 masl).
- The Whale Tail Pit is refilled by local catchment runoff, runoff from the IVR WRSF Contact Water Management System, and overflow of the Whale Tail Attenuation Pond and of the IVR Pit. Once Whale Tail Pit is refilled, the water surface elevation increases until Whale Tail Lake (North Basin) reaches the water surface elevation of 153.5 masl.

Using this approach, refilling of Whale Tail Lake (North Basin) to 153.5 masl is estimated to occur by 2042.

Reconnection of the South Basin and North Basin and Mammoth Lake will occur once water quality objectives are met within Whale Tail Lake (North Basin), the predictions of which are presented in the corresponding water quality modelling report (Golder 2021). However, this timeline will be updated via water quality modelling and operations management with the aim of matching the timing of end of flooding with meeting of water quality objectives.

The reflooding strategy will be adapted during closure based on future water quality predictions validated with site monitoring data. The goal will be for pit lake water to meet quality objectives concurrently with completed reflooding such that lake reconnection can happen as soon as possible thereafter.

## 6.0 CLOSURE

This report presents methods and results of the Project's updated mean annual water balance with a focus on the operation and closure phases of the Project for annual reporting purposes. It is limited to the catchments of the Project footprint and does not address the receiving environment within and downstream of the effluent discharge point.

Please do not hesitate to contact the undersigned should you have any questions or comments.

### WORKING DOCUMENT

#### WHALE TAIL EXPANSION PROJECT DESIGN DOCUMENT – WATER BALANCE AND WATER QUALITY MODEL INPUT PARAMETERS AND ASSUMPTIONS

This document provides the design basis assumptions used by Golder Associates Ltd. (Golder) for the Whale Tail Project water balance and water quality modelling in support of the 2020 Annual Reporting. These data have largely been provided by Agnico Eagle Mines Limited (Agnico Eagle) either specifically for the Expansion Project, carried over from the Approved Project, or have been derived from these data.

This is meant to be a working document for both Agnico Eagle and Golder to record changes in design or management plans occurring during the period of study. This document is organized into the following sections:

- 1) Mine Design Parameters
- 2) Water Balance Criteria and Assumptions

Annexes provide additional information and calculations made by Golder based on information received.

## 1.0 DESIGN PARAMETERS

**Table 1: Design Version Identification**

Document Revision No.	Date	Design Features	Agnico Eagle Version No.	Reference
01	19-Feb-18	Whale Tail Pit	WHL-001-009C	Base Case for EIS
		IVR Pit	IVR-001-004	
		Underground	AMQMY17UG003	
02	07-May-18	Same as above	Same as above	Base Case for EIS
03	04-July-19	Whale Tail Pit	Same as above	Base Case for EIS
		IVR Pit	Same as above	Base Case for EIS
		Underground – New Permafrost Plan C1	AMQMY18UG0012	Salvage Plan C1

**Table 2: Mine Design Criteria**

Infrastructure	Whale Tail	IVR	Total
Life of Mine	Construction: Q4 2017 to Q3 2019 Pit Operation: Q3 2019 to end Q4 2025 UG Operation: Q3 2019 to end Q4 2025 Closure: Q1 2026 to Q3 2041	Pit Operation: Q3 2020 to end Q4 2025 Closure: Q1 2026 to Q3 2041	Construction and Operations: Q4 2017 – end Q4 2025 Closure: Q1 2026 to Q3 2041
Open Pit Depth	275.3 m depth, from -129 to 146.3 masl	103.3 m depth, from 46 to 149.3 masl	-
Open Pit - Ore, total mined (t)	16,835,533	2,907,063	19,742,595
Open Pit - Waste rock total mined (t)	137,977,416	27,619,187	165,596,603
Open Pit - Overburden total mined (t)	7,619,698	3,723,876	11,343,574
Underground – Ore, total mined (t)	3,345,321	-	3,345,321
Underground – Waste rock total mined (t)	1,566,530	-	1,566,530
Waste Rock Storage Facility (t)	-	-	174,413,680
Waste Rock Storage Facility maximum height (metres above ground)	95 metres	85 metres	-
Underground Waste Rock Storage Facility height (meters above ground)	35 metres		-
Underground Waste Rock Storage Facility surface area	3.8 ha		-
Whale Tail Ore stockpile surface area (1, 2, 3 combined)	22.3 ha		-
Underground Ore Stockpile surface area	1.0 ha		-
Overburden Area	1.8 ha		-
NPAG WRSF Storage Area	20 ha		-

MT = million tonnes

**Table 3: Construction and Operation Schedule**

Dewatering/Construction/Operation Activities	Starts at Beginning of	Ends at the End of
GSP-1 Construction-Operation	Q4 2017	Q4 2025
Whale Tail Pit Quarry 1 Operation	October 2017	June 2020
Sewage Treatment Plant	2017	Closure
Underground Ramp/Mine Construction-Operation	Q1 2018	Q4 2025
Whale Tail Pit (Starter Pit) Operation	July 2018 (prior to the start of the water balance)	May 2020
Whale Tail Dike Construction and Operation	June 2018	Post-Closure
Pipeline and Effluent Discharge Diffuser in Mammoth Lake	Q4 2018	Q4 2025
Whale Tail Waste Rock Storage Facility Dike Construction and Operation	October 2018	Post-Closure
Mammoth Dike Construction and Operation	November 2018	Post-Closure
Northeast Dike Construction and Operation	January 2019	September 2020
Operational Water Treatment Plant (AsWTP)	March 2019	Q4 2025
North Sump Construction/Operation	June 2019	Q4 2025
Pipeline and Effluent Discharge Diffuser in Whale Tail (South Basin)	Q3 2019	Q4 2025
Whale Tail Dike Seepage Collection System	January 2020	Q4 2025
Whale Tail Lake (South Basin) Diversion Channel Construction	April 2020	April 2020
Whale Tail Attenuation Pond Operation	June 2020	Q4 2025
Lake A53 Diversion Operation	June 2020	Q4 2025
Whale Tail Pit Operation (Quarry 1 and Starter Pit merge into one open pit and to end of Life-Of-Mine)	July 2020	Q4 2025
IVR Pit Operation	September 2020	Q4 2025
IVR Diversion Operation	July 2020	Q4 2025
IVR WRSF Operation	July 2020	Q4 2025
Lake A53 Drawdown	Prior to Freshet 2021	Prior to Freshet 2021
IVR Attenuation Pond	June 2021	Q4 2025
Mammoth Sill and Spillway Construction and Operation	January 2026	In perpetuity
Closure	January 2026	Post-Closure (Mammoth Lake Sill overtopped)
Decommissioning of Ore Stockpiles	Closure	Q2 2027
Decommissioning of Landfarm	Closure	Q1 2040
Post - Closure	Mammoth Lake Sill overtopped	In perpetuity

**Table 4: Mine Plan**

Year	Underground (Salvage C1)		Whale Tail		IVR	
	Ore (tonnes)	Waste Rock (tonnes)	Ore (tonnes)	Waste Rock (tonnes)	Ore (tonnes)	Waste Rock (tonnes)
2018	0	0	179,003	981,556	0	0
2019	0	65,099	2,196,993	17,118,752	0	0
2020	276	229,272	2,825,211	28,218,266	244,910	1,130,804
2021	46,461	366,352	3,046,689	26,789,634	125,651	4,112,738
2022	380,002	278,057	2,992,263	26,638,663	775,982	4,470,156

2026	370,183	0	0	0	0	0

## 2.0 WATER BALANCE CRITERIA AND ASSUMPTIONS

**Table 5: Climate Assumptions**

Item	Assumption	Reference
Climate Data	Average year	Agnico Eagle, 2016b
Undercatch	<ul style="list-style-type: none"> <li>■ Rain undercatch = 1.15</li> <li>■ Snow undercatch = 1.55</li> </ul>	Agnico Eagle, 2016a (Amendment/Reconsideration of the Project Certificate and Amendment to the Type A Water Licence. Volume 6, Appendix 6-C. Submitted to the Nunavut Impact Review Board, June 30, 2016.)
Frozen Conditions	<ul style="list-style-type: none"> <li>■ October to May. Rainfall during frozen conditions is applied as rainfall in June of the same year if fallen between January and May inclusively, or during June of the following year if fallen between October and December inclusively.</li> <li>■ Snowfall outside of frozen conditions is applied as rainfall during the same month.</li> </ul>	assumed
Ice formation	<p>Formation of a maximum of 2 m of ice thickness over waterbodies every winter. All ice volume is removed instantly from active storage on October 1 and restored (i.e., melted) gradually over 30 days starting May 1.</p> <p>Note: A gradual build up time series does exist but causes the model to run extremely slowly so instant build up is being used, without implications on the results.</p>	Based on Golder Hydrology baseline as well as professional experience in northern climates. Intended to be conservative.
Infiltration Losses	Infiltration losses are assumed to be negligible in natural areas based on permafrost conditions.	assumed
Runoff from: <ul style="list-style-type: none"> <li>■ Whale Tail WRSF</li> <li>■ IVR WRSF</li> <li>■ Underground WRSF</li> <li>■ NPAG stockpile</li> </ul>	<ul style="list-style-type: none"> <li>■ Percentage of total annual precipitation over the footprint, by month:                             <ul style="list-style-type: none"> <li>■ October through May: 0%</li> <li>■ June: 4.3%</li> <li>■ July: 0.3%</li> <li>■ August: 0.3%</li> <li>■ September: 0.1%</li> </ul> </li> <li>■ Total annual precipitation was calculated as 323.022 mm/yr. This is not accounting for evaporative losses; it assumes evaporative losses were taken into account in O'Kane results.</li> <li>■ Basal seepage assumed to be negligible.</li> <li>■ Interflow is small and occurs past the modeling time period. This may need to be revisited.</li> </ul>	O'Kane Consultants, 2019
Runoff from ore stockpiles and construction material stockpile (esker material)	Calculated as per the previous water balance (i.e., does not use O'Kane inputs)	

**Table 6: Average Year Climate Data Used in the Site Water Balance**

Month	Rainfall (mm/mon)	Lake Evaporation (mm/mon)	Evapotranspiration (mm/mon)	Snowfall (mm/mon)	Sublimation (mm/mon)
January	0	0	0	6.88	9
February	0	0	0	6.24	9
March	0	0	0	9.11	9
April	0	0	0	13.29	9
May	0	0	0	8.09	9
June	33.36	9	3	0	0
July	38.51	99	32	0	0
August	42.74	100	32	0	0
September	41.47	40	13	0	0
October	0	0	0	22.45	9
November	0	0	0	16.59	9
December	0	0	0	9.95	9

**Table 7: Site Water Balance: Modelled Flows**

Location	Description of Inflows
Quarry 1	<ul style="list-style-type: none"> <li>■ Natural runoff and direct precipitation (Q4 2017 – WTN Dewatered)</li> <li>■ Runoff from Starter Pit (July 2018 – WTN Dewatered)</li> <li>■ Pumped water from WT WRSF System (Q2 2018 – WTN Dewatered)</li> <li>■ Pumped water from Industrial Sector, Overburden Sector and Camp Sector (Q2 2018 – WTN Dewatered)</li> <li>■ Drilling water from Nemo Lake (Q4 2017 to August 2018)</li> </ul>
GSP-1 (formerly AP5)	<ul style="list-style-type: none"> <li>■ Natural runoff and direct precipitation (2018 – Post Closure)</li> <li>■ Runoff from the WERP waste rock pad (2019 – Closure)</li> <li>■ Excess underground contact water pumped from the underground (2018 – Q4 2025)</li> <li>■ Overflow from the Whale Tail Attenuation Pond (October 2019 – May 2020)</li> </ul>
Underground Mine	<ul style="list-style-type: none"> <li>■ Natural runoff from the portal catchment area (2018 – Post Closure)</li> <li>■ Make-up water from Nemo Lake (2019 – Closure)</li> <li>■ Recirculation of consumptive flows assuming</li> <li>■ 100% re-use post water loss to ore and waste rock from January 2018 to June 2020</li> <li>■ 95% re-use post water loss to ore and waste rock (July 2020 – Closure)</li> <li>■ Water loss at a rate of 3% water content by weight of extracted ore and waste material</li> <li>■ No Groundwater inflow as mining is assumed to occur completely within the permafrost</li> <li>■ Excess underground contact water pumped to GSP 1</li> <li>■ Drawdown of Whale Tail Lake (South Basin) (Closure)</li> <li>■ Drawdown of the IVR Attenuation Pond, GSP-1 and GSP-2 (Closure)</li> </ul>
Northeast Sector	<ul style="list-style-type: none"> <li>■ Natural runoff from catchment area (2018 – Post Closure)</li> <li>■ Runoff from Lake A49 (2018 – July 2020)</li> </ul>

**Table 8: Water Storage Assumptions**

Pond	Feature	Value	Reference
Quarry 1	Capacity	203,450 m <sup>3</sup>	Golder Water Balance, 2019a
GSP-1 (formerly AP5)	Capacity	148 601 m <sup>3</sup>	
	Spill Elevation	153.9 masl	
Underground	Capacity	In closure: 651,000 m <sup>3</sup>	
	Spill Elevation	149.0 masl	
Underground Stope	Capacity	0 m <sup>3</sup>	
Whale Tail Attenuation Pond	Capacity	Dewatered to closure: 117,857 m <sup>3</sup>	
	Spill Elevation	143.5 masl	
IVR Attenuation Pond (formerly Lake A53)	Capacity	Up to 2021: 160,051 m <sup>3</sup> 2022 – Q4 2026: 413,000 m <sup>3</sup>	
	Spill Elevation	Up to 2022: 161.73 masl 2022 – Q4 2025: 163.9 masl	
Northeast Sector Pond (Managed at baseline levels)	Capacity	33,785 m <sup>3</sup>	
	Spill Elevation	Baseline: 154.40 m	
Whale Tail Waste Rock Storage Facility Pond	Capacity	Operations: 244,580 m <sup>3</sup> Closure: 1 m <sup>3</sup> (intended to act as a flow-through system)	
	Spill Elevation	158.4 masl	
IVR Waste Rock Storage Facility Ponds	Capacity	1 m <sup>3</sup> (intended to act as a flow-through system)	
Whale Tail Lake (South Basin)	Capacity	Baseline: 4,597,768 m <sup>3</sup> Flooded: 11,832,960 m <sup>3</sup> Post Closure: 5,547,803m <sup>3</sup>	
	Spill Elevation	Baseline: 152.5 masl Flooded: 156.0 masl Post Closure: 153.5 masl	
Whale Tail Lake	Capacity	Baseline: 10,516,453 m <sup>3</sup> Post Closure: 12,719,584m <sup>3</sup>	
	Spill Elevation	Baseline: 152.5 masl Post Closure: 153.5 masl	
Mammoth Lake	Capacity	5,717,693 m <sup>3</sup>	
	Spill Elevation	152.5 masl	

**Table 9: Consumptive Flows**

Item	Flow Rate	Source
Camp Use	As recorded (2020) 0.24 m <sup>3</sup> /person/day (January 2021 to end of operations) January 2021 to end of operations: 544 people Closure: 50 people	Whale Tail Lake (South Basin) (January – August 2018 and closure) Nemo Lake (Lake C38) (September 2018 - end of operations)
Truck Shop	As recorded (2020) 103.1 m <sup>3</sup> /day (January 2021 - end of operations)	Whale Tail Lake (Q1 – Q2 2018 (until Quarry 1 is mined out) Whale Tail Lake (South Basin) (July, August 2018) Nemo Lake (September 2018 – end of operations)
Drilling Water, per pit	As recorded (2020) 48.0 m <sup>3</sup> /day (2021 - end of operations)	Whale Tail Lake (2017 - Q1 – Q2 2018 (until Quarry 1 is mined out) Whale Tail Lake (South Basin) (July, August 2018) Nemo Lake (September 2018 – February 2019) Mammoth/Lake A47/Meadow River (March 2020 – December 2020) Nemo Lake (2021 – end of operations)
Ore moisture content from pits	1% of ore tonnage	Loss from system
Waste rock moisture content from open pits	1% of waste rock tonnage	Loss from system
Ore moisture content from underground	3% of ore tonnage	Loss from system
Waste rock moisture content from underground	3% of waste rock tonnage	Loss from system
Dust Control	As recorded (2020) 72,240 m <sup>3</sup> /yr (2021 - end of operations)	Loss from AP5 (not included as inflow to site) (2020) Loss from Nemo Lake (not included as inflow to site) (2021 - end of operations)
Emulsion Plant	2.9 m <sup>3</sup> /day	Loss from Mammoth Lake
Underground recirculation percent	95%	Underground sump
Underground consumptive flows	2019: 396.9 m <sup>3</sup> /day 2020: 672.7 m <sup>3</sup> /day 2021: 852.1 m <sup>3</sup> /day 2022: 921.2 m <sup>3</sup> /day 2023: 860.8 m <sup>3</sup> /day 2024: 802.0 m <sup>3</sup> /day 2025: 757.8 m <sup>3</sup> /day 2026: 357.1 m <sup>3</sup> /day	Demand for water use underground supplied primarily through recirculation of underground water, groundwater inflows, and makeup water from Nemo Lake or GSP1 if required.

**Table 10: Water Treatment Rates**

Treatment Type	Dates	Water Flow
Sewage Treatment Plant (STP)	Model start to end of closure	See Table 9

SSWQO	Site Specific Water Quality Objective
STP	Sewage Treatment Plant
TDS	Total Dissolved Solids
TSS	Total Suspended Solids
WRSF	Waste Rock Storage Facility

## 1.0 INTRODUCTION

Agnico Eagle Mines Limited Meadowbank Division (Agnico Eagle) is currently operating the Whale Tail satellite deposit on the Amaruq exploration property, which is a 408-square kilometre (km<sup>2</sup>) site located on Inuit-owned Land approximately 150 kilometres (km) north of the hamlet of Baker Lake and approximately 50 km northwest of the Meadowbank Mine, in the Kivalliq region of Nunavut (Figure 1). The property was acquired by Agnico Eagle in April 2013 subject to a mineral exploration agreement with Nunavut Tunngavik Incorporated.

The Expansion Project supports ore extraction from two open pits (i.e., Whale Tail Pit and IVR Pit), with underground mine development, over an eight-year mine life. Waste rock and overburden will be stored in the Whale Tail Waste Rock Storage Facility (WRSF), IVR WRSF, and Exploration Pad WRSF; excess non potentially acid generating or non-metal leaching (NPAG/NML) waste rock will be segregated and stockpiled separately (Agnico Eagle 2021). The ore is being trucked to the existing mill in the Portage area of the Meadowbank Mine for processing, and tailings are being deposited in the existing Meadowbank Mine tailings storage facility.

Golder Associates Ltd. (Golder) has completed the following water quality models:

- Approved Project, completed in 2016 (Agnico Eagle 2016a) and updated in 2017 (Golder 2017a), to support the Environmental Assessment (EA) and Water Licence Type A Application for the Whale Tail Pit;
- Water Licence B Application in 2016 for the Advanced Exploration and Bulk Sampling of the Amaruq Exploration Site (Golder 2016);
- EA for the Expansion Project (Golder 2018a), using the same modelling platform as the Approved Project, but informed by additional purpose-built and more detailed models to address issues raised during the Approved Project EA;
- Water Licence Type A Amendment Application for the Expansion Project (Golder 2019a); and,
- 2019 Annual Report (Golder 2020).

Agnico Eagle retained Golder to forecast the probable quality of mine contact water to support the 2020 Annual Report, as mandated in Part E, Items 5 and 6 of the Type A Water Licence 2AM-WTP1830:

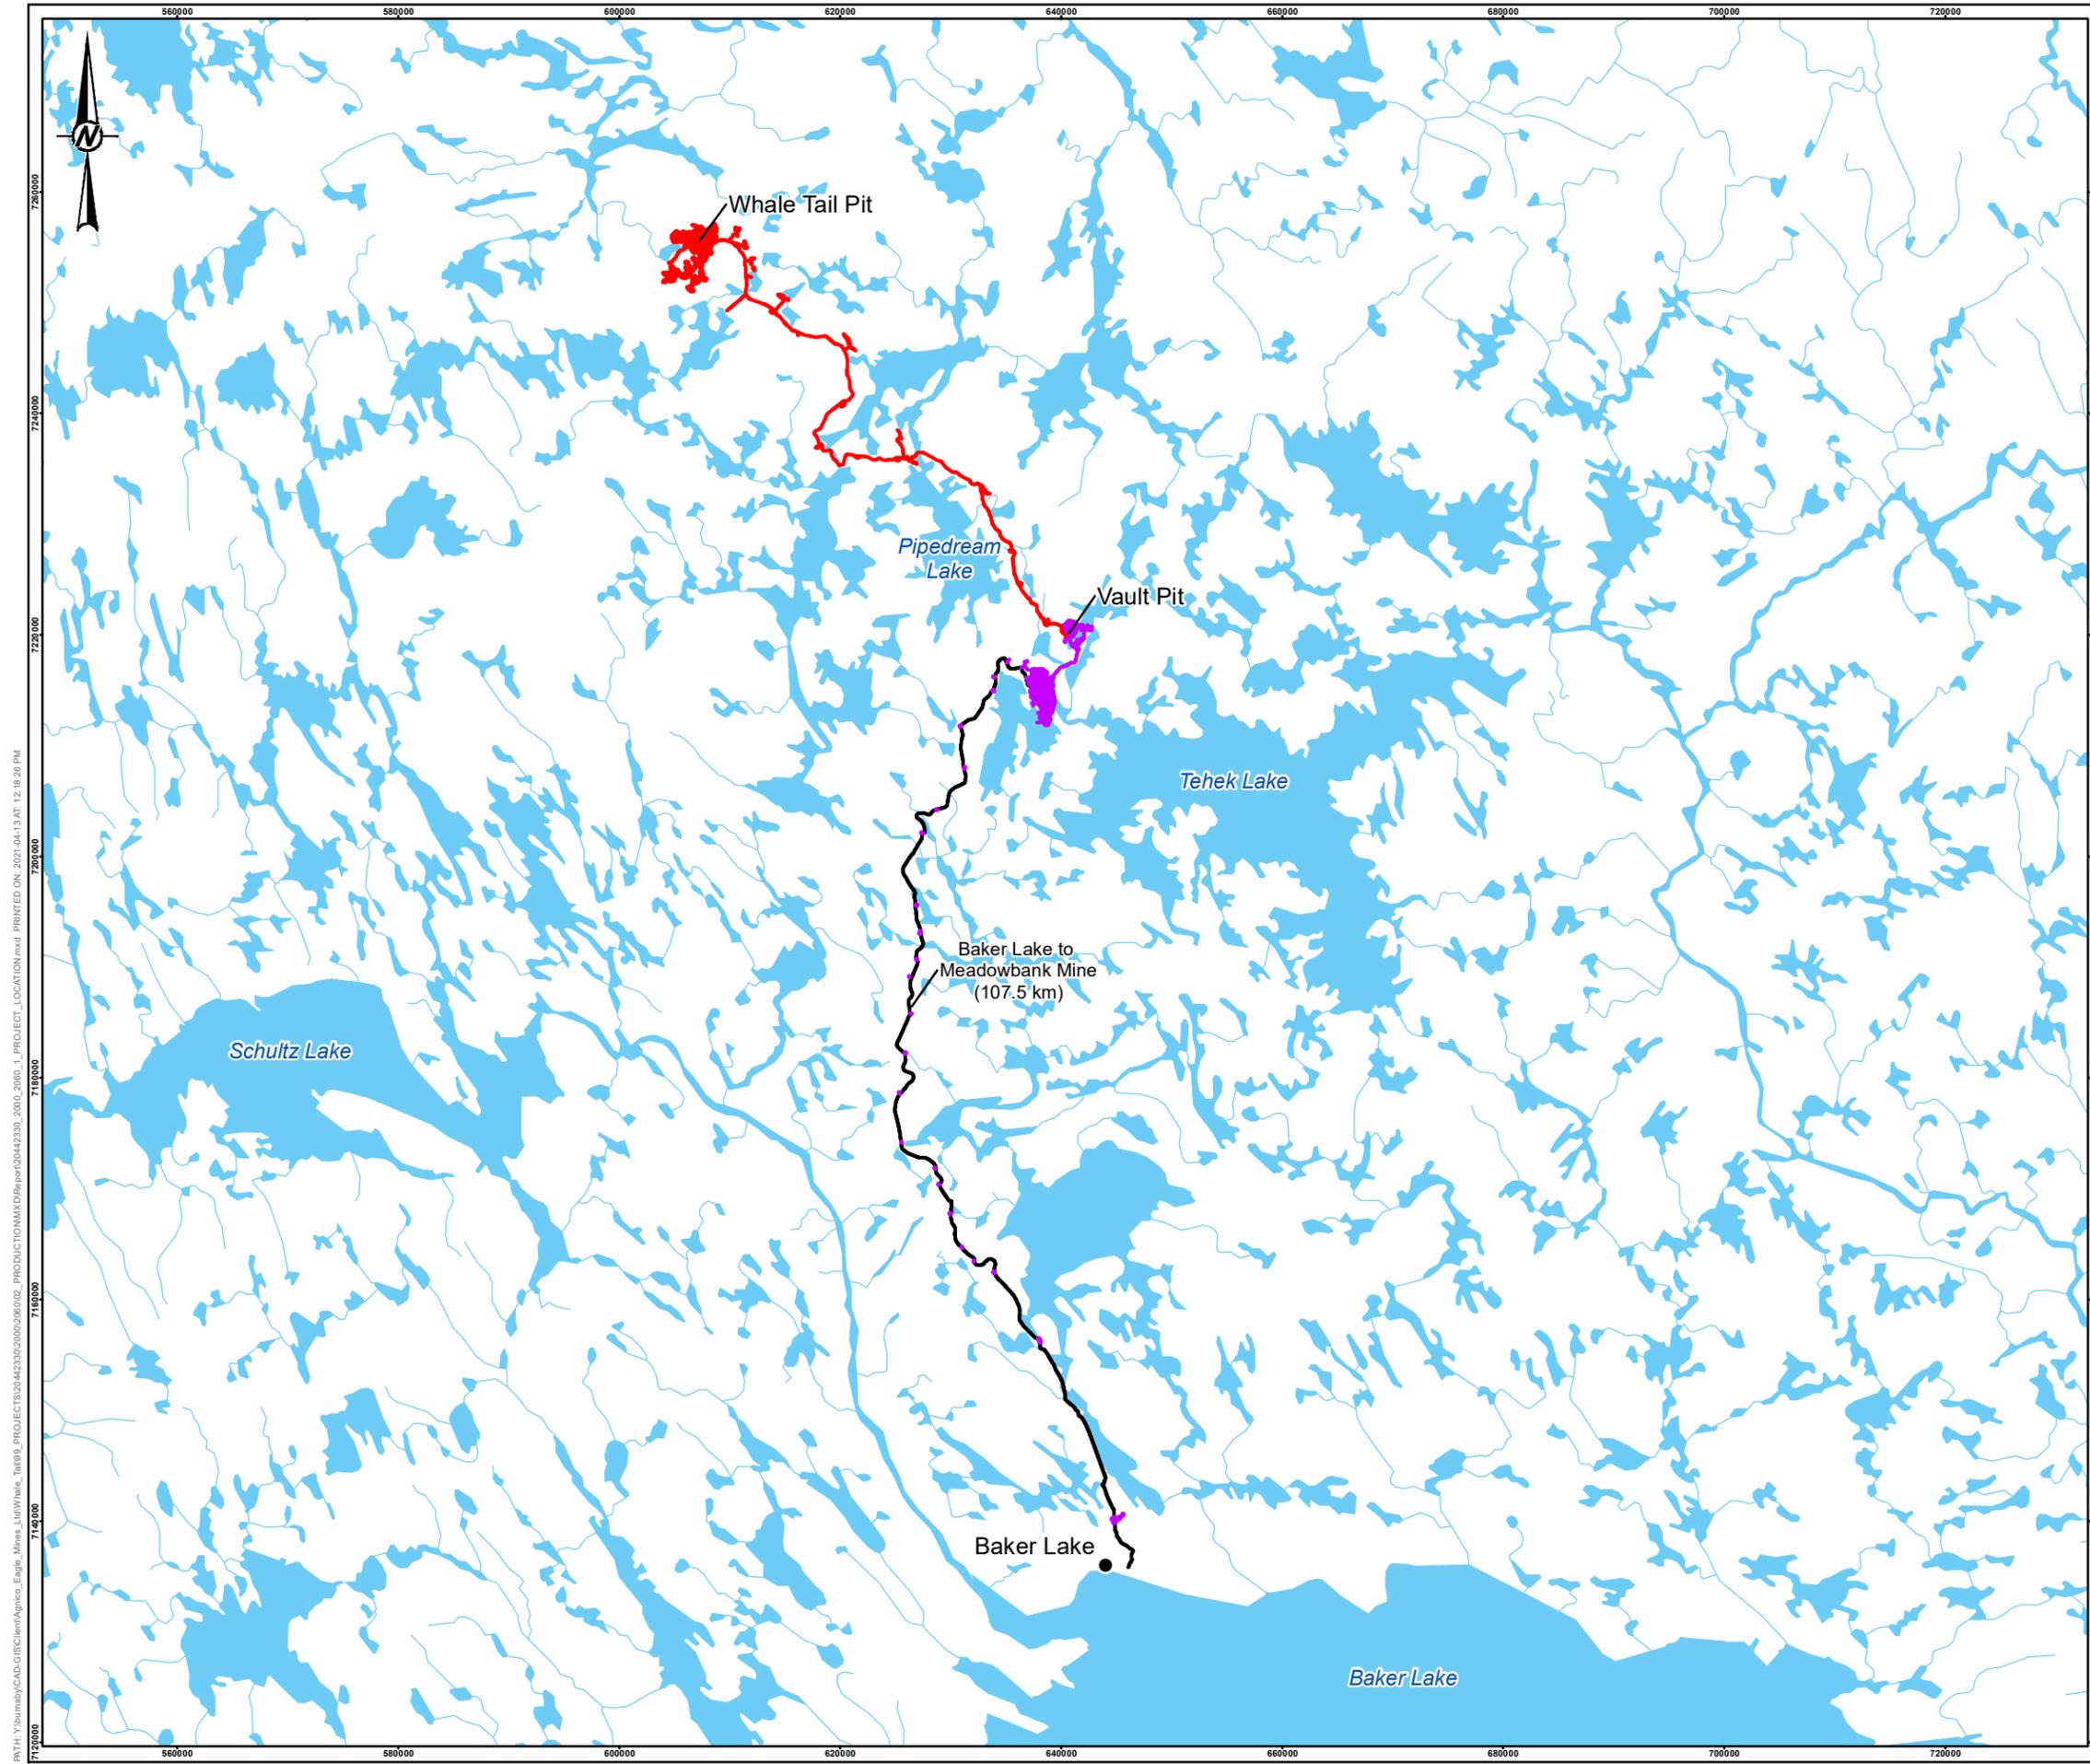

*“5. The Licensee shall submit an updated Water Management Plan on an annual basis to the Board for review following the commencement of Operations. The Plan must include an updated Project Water Balance. The Water Management Plan shall include an action plan to be implemented if predicted re-flooded pits water quality indicates that treatment is necessary.*

*6. The Licensee shall submit a Water Quality Model for pits re-flooding and for Waste Rock Storage Facilities’ contact water mixing into Mammoth Lake post-Closure as part of the Water Management Plan. The Water Quality Model shall be re-calibrated as necessary and updated annually following commencement of Operations. The results and implications of the predictive model shall be reported to the Board.”*

For the 2020 Annual Report the water balance model from the 2019 Annual Report was updated to include the following:

- Recorded water transfers in 2020;
- 2020 climate data from the Baker Lake weather station; and,
- Facilities that are part of the Expansion Project, as per the model used to support the Type A Water Licence Amendment for the Expansion Project (Golder 2019a).

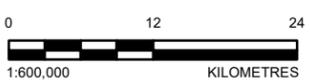

This report documents a brief discussion of the water quality trends on site, the modelling approach, and a summary of the water quality forecasts of the Expansion Project components and downstream receiving environment.

## 2.0 MODELLING APPROACH

The water quality model was completed using GoldSim software version 12.1 (GoldSim 2018). GoldSim is a graphical, object-oriented mathematical model where all input constituents and functions are defined by the user and are built as individual objects or elements linked together by mathematical expressions. The object-based nature of the model is designed to facilitate understanding of the various factors, which control an engineered or natural system and predict the future performance of the system. The water quality model integrates a mass balance model with the water balance model for operations, closure, and post-closure (Golder 2021). Each flow that could influence site discharge water quality for the Expansion Project was itemized and assigned a source term chemical profile based on geochemical testing of waste rock materials, observed mine site facility water quality at the Meadowbank Mine surface operations (informed by existing explosives management practices), baseline surface water quality monitoring data, and site groundwater monitoring data.

In the water quality model, Expansion Project facilities that accumulate water (e.g., water management ponds, pits, and sumps) are treated as distinct collection ponds within the model. Inflow volumes and concentrations or mass loads are included as inputs to each collection pond to account for chemical loadings from natural areas, developed areas, waste rock runoff and seepage, pit wall rock runoff, and groundwater inflows, to project the chemistry of contact water quality that is sourced from each of these mine facilities.

The water quality model is designed to estimate these chemistries as a monthly average concentration, from construction (2018 – 2019), through operations (2019 – December 2025), closure (January 2026 – August 2041), into post-closure (September 2041+). It simulates the chemistry of the following water quality constituent groups:

- Major ions: calcium, chloride, fluoride, magnesium, potassium, sodium, and sulphate
- Nutrients: nitrate, total ammonia, and total phosphorus
- Dissolved metals: mercury, silver, aluminum, arsenic, barium, beryllium, boron, bismuth, cadmium, cobalt, chromium, copper, iron, lithium, manganese, molybdenum, nickel, lead, antimony, selenium, strontium, tin, thallium, uranium, vanadium, and zinc

Total dissolved solids (TDS) was not modelled but is calculated externally using the predictions of major ions as per the APHA (2017).

Total constituent concentrations are calculated based on modelled dissolved concentrations for on-site facilities, accounting for a particulate fraction for each constituent based on a total suspended solids (TSS) concentration and associated geochemical testing, which is added to the modelled dissolved concentrations. These total constituents were tracked as they mixed in the downstream receiving environment without accounting for any settling out of particulate matter.

This report focuses primarily on those modelled constituents that have Effluent Quality Criteria (EQCs) or Canadian Environmental Quality Guidelines for the Protection of Aquatic Health (CEQG-PAL) (CCME 2007).

## 2.1 Model Setup

The operational, closure, and post-closure mine site water balance for the Expansion Project was completed and documented in the Water Balance Report (Golder 2021). For operations, the following infrastructure components represent prediction nodes of mine site water quality:

- Open pit sumps:
  - Whale Tail Pit: Receives pit wall runoff, natural catchment runoff, direct precipitation on the sump pond surface, drilling fluids, and groundwater inflows, which are a combination of regional groundwater, Whale Tail Lake (South Basin) water, and Whale Tail Attenuation Pond water.
  - Quarry 1 (this becomes part of Whale Tail Pit in June 2020): Began development in late 2017 and acted as a collection point for all site contact water until June 2020. It also receives natural catchment runoff, pit wall runoff, and drilling fluids.
  - IVR Pit: Receives pit wall runoff, natural catchment runoff, direct precipitation on the sump pond surface, and drilling fluids. IVR Pit is located entirely within permafrost and is therefore assumed to have no groundwater inflows.
- Waste Rock Storage Facilities' Contact Water Collection Systems (WRSF Ponds):
  - Whale Tail WRSF Pond: Receives natural runoff from the catchment area, runoff from the Whale Tail WRSF and a submarginal ore stockpile, and direct precipitation.
  - IVR WRSF Pond: Receives natural runoff from the catchment area, runoff from the IVR WRSF, and direct precipitation.
- Attenuation Ponds:
  - Quarry 1 (until June 2020)
  - Whale Tail Lake (North Basin) / Whale Tail Attenuation Pond: Prior to May 2020, Whale Tail Lake (North Basin) was being dewatered and received only catchment inflows and dike seepage water. Once dewatered in May 2020, it began receiving all site contact water, which will continue through May 2021. During this period it also receives natural catchment runoff (natural runoff and lakebed sediment runoff), direct precipitation, treated sewage effluent, and groundwater inflows, which are a combination of regional groundwater and Whale Tail Lake (South Basin) water.
  - IVR Attenuation Pond: Receives all site contact water beginning in June 2021, through the end of operations. It also receives natural catchment runoff, direct precipitation, and treated sewage effluent. It does not receive any groundwater inflows
  - Groundwater Storage Pond -1 (GSP-1): Serves as temporary contact water storage in the summer months of 2020, but is subsequently dewatered, thereafter collecting contact water from the Exploration Pad WRSF and ore stockpiles, as well as excess saline water from the underground operations.
- The Operations Water Treatment Plant (AsWTP) effluent
- Receiving environment:
  - Mammoth Lake (Lake A16), see Figure 2
  - Whale Tail Lake (South Basin) (Lake A17)
  - Downstream (DS) Node 1 and DS Node 2, see Figure 2

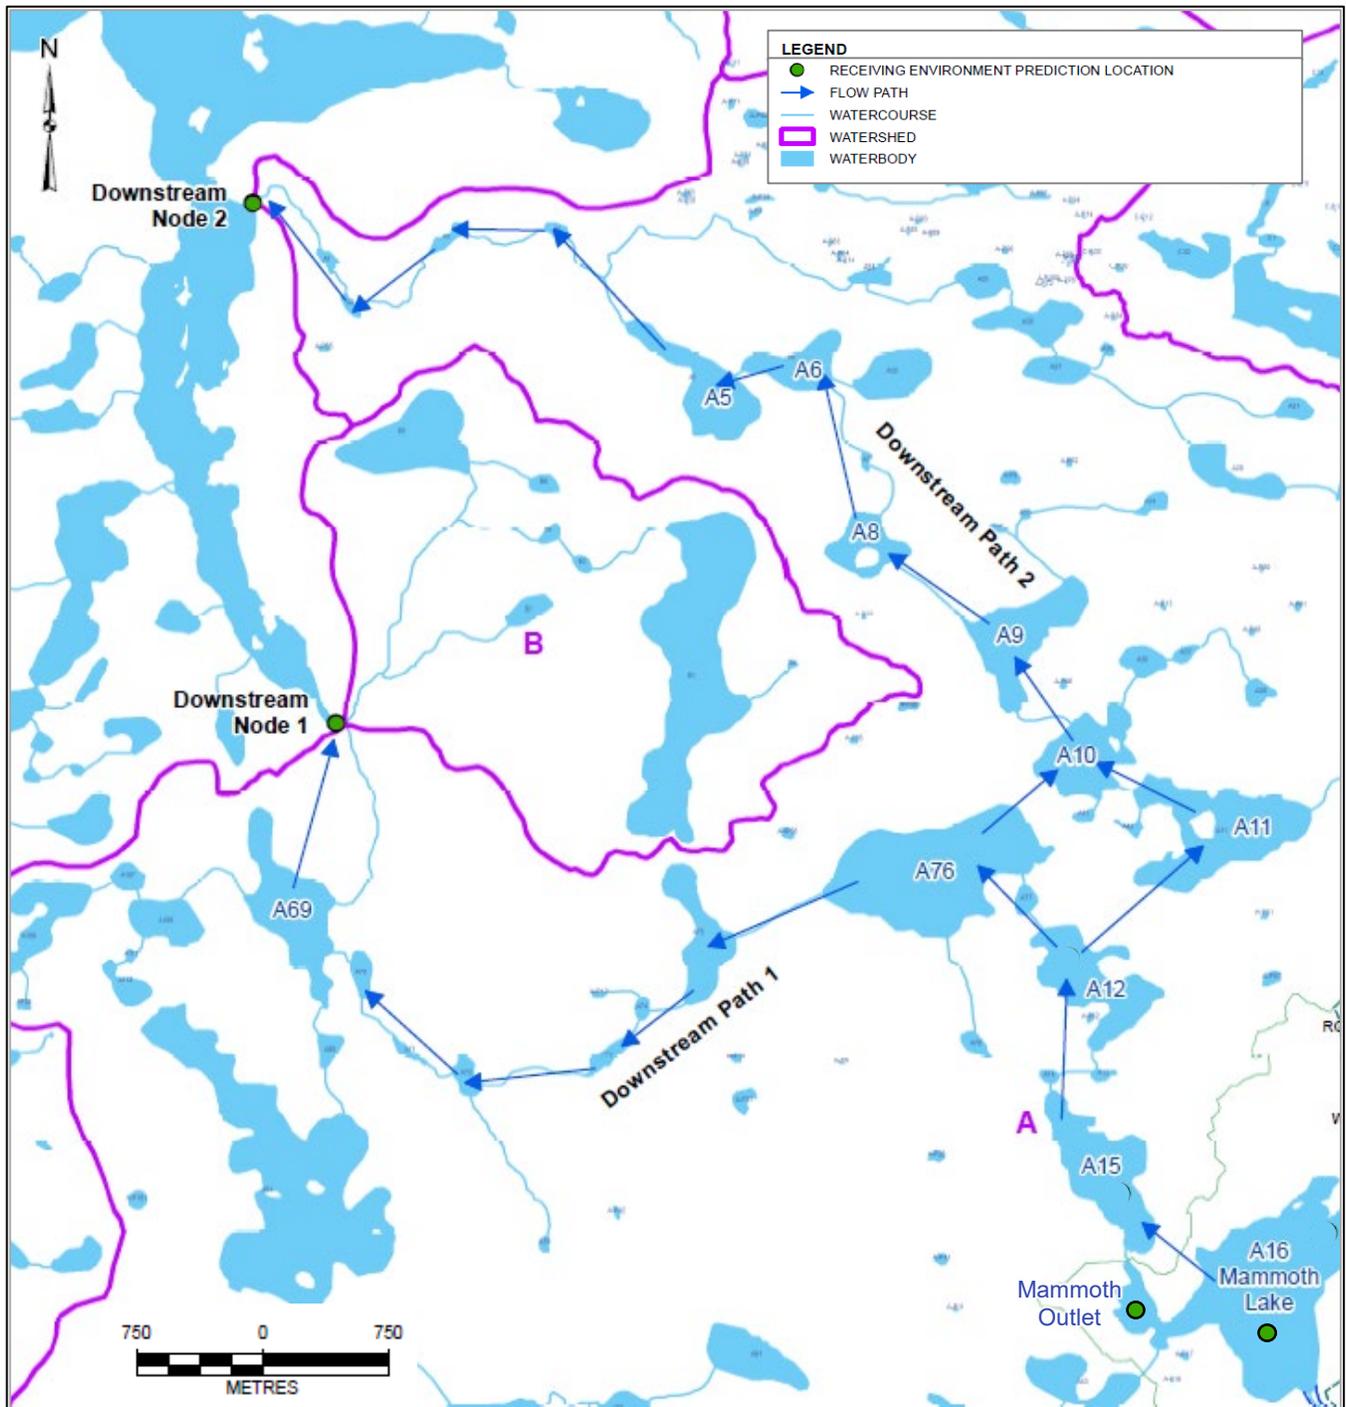

Figure 2: Receiving Environment Flow Paths and Prediction Locations

In general, water management on site can be separated into:

- Surface contact water flows, which are ultimately managed through the Whale Tail Attenuation Pond and the IVR Attenuation Pond:
  - Runoff from constructed pads
  - Runoff from ore stockpiles
  - Pit wall runoff in the Whale Tail and IVR Pits
  - Groundwater inflows to the Whale Tail Pit and to the Whale Tail Attenuation Pond
  - Runoff from the Whale Tail WRSF, IVR WRSF, and NPAG WRSF
  - Sewage Treatment Plant (STP) effluent
  - Landfarm runoff
- Saline water flows, managed in GSP-1:
  - Runoff from the Exploration Pad WRSF and underground ore stockpiles
  - Excess saline water from the underground operations
- Non-contact flows:
  - Diverted natural catchment runoff (i.e., Northeast Sector)
  - Lake dewatering flows (i.e., Whale Tail Lake [North Basin], Lake A47, Lake A49, Lake 50, Lake 51, Lake A53)
  - Dike seepage, which is collected separately and can be discharged directly without requiring treatment, if water quality criteria are met

The effect on water quality from materials present in ditches, dikes, berms, and other water retaining structures is expected to be insignificant compared to contact water sources; as such, loading from these sources was considered negligible and not accounted for in the site water quality model.

### 2.1.1 Updates Applied for 2020

General site water quality and chemical loading rate inputs and assumptions have been maintained from the 2019 Annual Report Water Quality Model update, with the following updates:

- General updates to the model were done to better align with monitoring data collected in 2020. The updates focussed on:
  - The Whale Tail WRSF Pond: Updated to represent seasonal processes as described in Section 3.1. The updates were also applied to the IVR WRSF Pond for predictions moving forward, under the assumption that similar seasonal processes would control the release of mass from the WRSF.
  - The Whale Tail Attenuation Pond: Because the Whale Tail Attenuation Pond collects all site contact water flows in 2020, the water quality was updated to reflect the overall effect of processes and trends occurring in facilities upstream of the Whale Tail Attenuation Pond (i.e., open pits, storage of water in Quarry 1 and GSP-1, intermediate sumps). This update was applied only to the active Attenuation Pond, that is, it was applied to the Whale Tail Attenuation Pond up to and including May 2021, and to the IVR Attenuation Pond thereafter.

- The AsWTP: In previous iterations of the water quality model, maximum concentrations for arsenic and phosphorus were applied at the AsWTP, at 0.1 mg/L and 0.05 mg/L, respectively. If predicted untreated concentrations were lower than these maximum limits, the model assumed no treatment would be applied. If the predicted untreated concentrations were higher than these maximum limits, the limits would be applied to the water entering the modelled downstream receiving lakes. Monitoring data for the AsWTP effluent generally show an increased treatment efficiency from what was previously assumed in the model. In order to align the predicted treated effluent concentrations with the monitored data, a treatment efficiency for each modelled constituent was developed based on monitoring data and applied to the modelled AsWTP influent. This treatment efficiency was applied to all water being discharged through the AsWTP, regardless of destination. The composition and lithological proportions of waste rock in the Whale Tail WRSF and exposed in the pit walls were updated to be consistent with the Expansion Project model.
- The delineation between groundwater quality sources (i.e., regional groundwater, lake-derived groundwater, or Whale Tail Attenuation Pond-derived groundwater) was updated to be consistent with the Expansion Project model.
- The areas of the WRSFs that contribute mass to the pond through runoff were updated to represent only the slope of the first bench. In previous iterations of the water quality model, it was assumed that the entire footprint of the WRSFs were interacting with the runoff collected in their respective collection ponds. However, a smaller area contributes mass to this runoff because the WRSF is designed to direct precipitation on the WRSF surface towards the centre of the pile where it becomes frozen, and only the runoff from the slope of the first bench is anticipated to flow to the pond (OKC 2019).
- The percentage of WRSF that is covered was updated to be reflective of the cover on the slope of the first bench. Cover material over the exposed waste rock controls how much of the pile runoff interacts with cover material relative to PAG/ML material. As a function of the entire footprint of the WRSF, the percentage cover material increases over the length of operations as progressive covering occurs. However, a small percentage of cover material over the full footprint in the first year may equate to nearly 100% coverage around the perimeter (the area that is being adjusted as per the point above).
- The application of TSS values from monitoring data, used to facilitate the calculation of total concentrations.
- Updated water quality inputs for the sewage treatment plant (STP) effluent, based on monitoring data from ST-WT-11 between January 1, 2020 and December 28, 2020 as noted in Table 1.

**Table 1: Updated nitrate, ammonia, and total phosphorus concentrations for the STP Effluent.**

Constituent	Unit	Previous Iterations	Current Iteration
Nitrate as N	mg/L as N	5.0	16.5
Ammonia as N	mg/L as N	Modelled freshwater quality	0.27
Total Phosphorus	mg/L	0.5	6.0

### 2.1.1.1 Updates to TSS Inputs

Much of the water quality data was only available for total concentrations. Therefore, to improve alignment of predicted and observed concentrations in the Whale Tail WRSF Pond, the Whale Tail Attenuation Pond, and the AsWTP effluent, observed TSS concentrations from monitoring data were applied directly into the model for 2020, with monthly TSS concentrations developed and applied for predictions (i.e., > 2020).

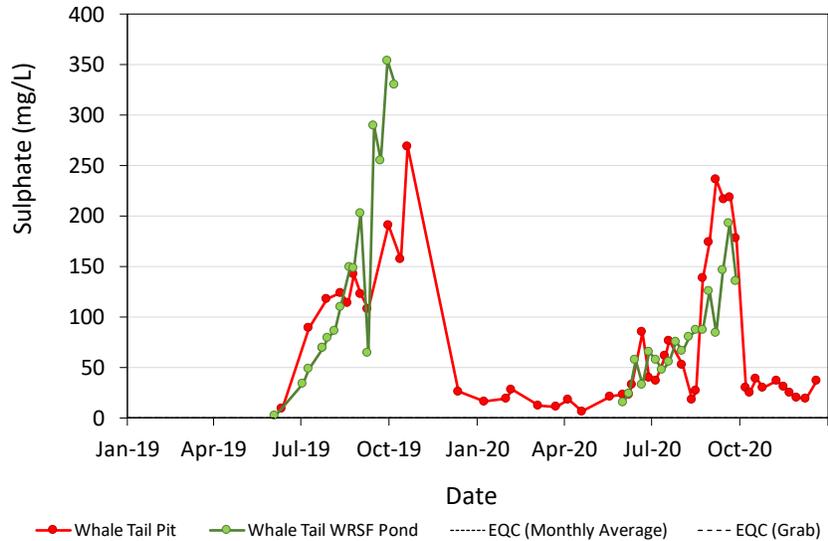

In previous iterations of the water quality model, a particulate fraction concentration for each constituent was applied to the predicted dissolved concentration in the effluent, as well as in the pit lake and Whale Tail WRSF runoff in post-closure, to estimate total concentrations. This particulate fraction was calculated based on solid geochemistry results and the anticipated proportion of each lithology that would be exposed over the entire length of operations. In the 2019 Annual Report, total concentrations in mine facilities were reported, based on an assumption of 15 mg/L of TSS, due to insufficient quantity of monitoring data. For effluent predictions moving forward, monthly average TSS concentrations, based on the available effluent monitoring data, were applied (Table 2).

Closure and post-closure assumptions of TSS concentrations remain consistent with previous iterations of the model, such that 10 mg/L of TSS is applied to the Whale Tail WRSF runoff in post-closure, and 1 mg/L of TSS is applied in the pit lake in post-closure.

**Table 2: Updated TSS concentrations (mg/L) applied in the model after observed data ends, based on monitored data.**

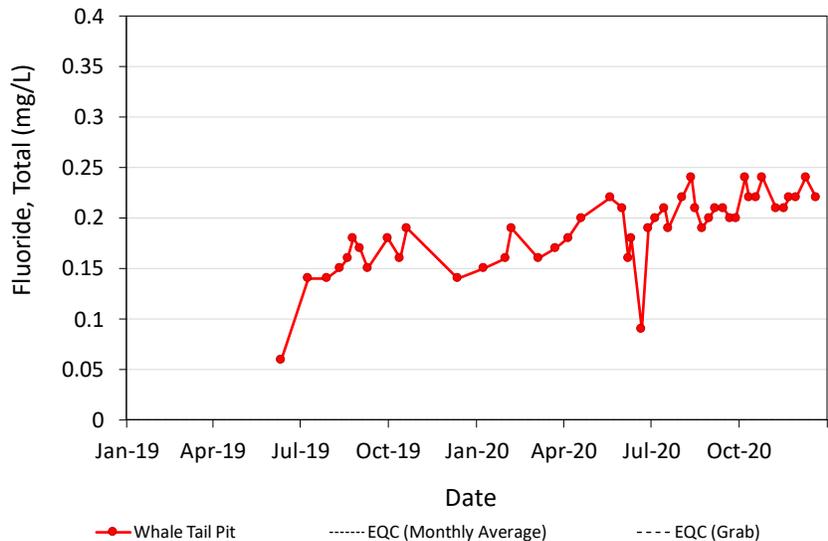

Month	Whale Tail WRSF Pond	Whale Tail Attenuation Pond	Treated Effluent
January	1	24	4.4
February	1	23	6.9
March	1	10	4.3
April	1	4.0	4.1
May	1	13	3.6
June	40	127	4.4
July	10	31	4.0
August	6.6	29	3.7
September	13	41	4.1
October	1	42	4.1
November	1	39	3.8
December	1	81	4.8

**Figure 4: Sulphate in the Whale Tail WRSF Pond (green) and the Whale Tail Pit (red), in 2019 and 2020. A seasonal trend displaying increasing concentrations throughout the summer months is visible.**

In contrast to these two major seasonal trends, some constituents do not show a visible trend throughout the summer months either due to all, or most, of the monitored data being below the detection limit, or due to a large degree of variability. In addition, some concentrations show a general trend over time that is not related to a seasonal influence. For example, fluoride concentrations do not show a strong seasonal variation (though there is some in June with freshet) but have been slowly and steadily increasing, particularly in the Whale Tail Pit (Figure 5).

**Figure 5: Fluoride in the Whale Tail Pit, in 2019 and 2020. A strong seasonal trend is not apparent, though concentrations are displaying a slow and steady increase.**

Water quality for 2019 and 2020, for the Whale Tail WRSF Pond, Whale Tail Pit, Whale Tail Lake (North Basin), Whale Tail Attenuation Pond, and GSP-1, are presented in Figure 6. Modelled constituents that have EQCs are presented, with pH and TDS additionally shown.

### 3.1 Whale Tail WRSF Pond

In 2019, the Whale Tail WRSF had not reached its ultimate footprint, and a wet season resulted in a higher amount of water needing management in the Whale Tail WRSF Pond. As such, water accumulated over the summer of 2019. In 2020, there was less water throughout the summer, and the pond was managed as intended, with very little volume stored.

Water quality trends in the monitoring data from the Whale Tail WRSF Pond show the two distinct patterns mentioned above. Occasional concentrations greater than the EQCs occur for TSS, total aluminum, total chromium, and total iron. Total concentrations of aluminum, chromium, and iron are closely tied to TSS concentrations, as their particulate fractions tend to be elevated compared to other metals. All other constituents remain below their respective EQCs.

### 3.2 Whale Tail Pit

In the Whale Tail Pit, it is anticipated that monitored water quality will differ between the summer months and winter months. In the winter, water quality should be representative of groundwater inflows as surface runoff does not occur, whereas in the summer, the surface runoff would impart more of an influence on the water quality. Between 2019 and 2020 as the Whale Tail Pit progressed from overburden stripping to the first few mine benches, there was high variability in the water quality for most constituents, such that the seasonal trends as described above are not entirely discernable. As more data is collected, any trends should become more apparent.

Total alkalinity, calcium, chloride, barium, and manganese are among some of the constituents that show higher concentrations in winter months and are likely controlled by inflowing groundwater. However, it is, as of yet, uncertain as to the specific origins of the groundwater that is entering the pit. It is likely a combination of regional groundwater, water from Whale Tail Lake (South Basin), and water from the Whale Tail Attenuation Pond; however, the proportions of each are unknown and require further investigation.

Certain constituents, such as sulphate, chromium, arsenic, molybdenum, and selenium appear to increase, or show more variability, over the summer months and remain lower, relative to the summer months, in the winter, indicating they are more likely controlled by the runoff over the pit walls. Total aluminum, chromium, and iron show good agreement with TSS concentration trends, and are frequently above the EQCs.

Finally, many of the constituents show an increase in concentrations in September 2020, though there is uncertainty regarding the source or mechanism.

### 3.3 GSP-1

Between June and September 2020, GSP-1 received flows from the underground portal area, its immediate catchment area (Exploration Pad), and pumped flow from the Whale Tail Attenuation Pond (in June). In September, GSP-1 was emptied to the Whale Tail Attenuation Pond.

A few constituents in the monitoring data (arsenic, aluminum, chromium, copper, iron) show a decrease in concentration over the summer. These concentrations are likely more closely tied to suspended solids, which also shows a decreasing trend. It is also likely that the initially higher concentrations are reflective of the water that was pumped to GSP-1 from the Whale Tail Attenuation Pond, which had higher concentrations of these constituents than GSP-1 in June.

The remaining available constituents, including major ions, explosives residues, and some metals, show an increase in concentration throughout the summer. These are more likely associated with flows from the underground portal and catchment runoff from the Exploration Pad WRSF and ore stockpiles. The increase in concentrations in most of these constituents is also seen in the Whale Tail WRSF Pond and the Whale Tail Pit.

### 3.4 Whale Tail Attenuation Pond

Once dewatering of Whale Tail Lake (North Basin) was complete, the Whale Tail Attenuation Pond collected water from contact water to the west of the Whale Tail Pit (collected just upstream of the Mammoth dike), the Whale Tail Pit, the Whale Tail WRSF Pond, IVR Pit (primarily dewatering flows from A47 and A49 as IVR Pit was initiated only in September), the STP effluent, runoff from its immediate catchment which includes developed areas, GSP-1 in September, and the dewatering of A53 in September. The water quality in Whale Tail Attenuation is reflective of the sources of contact water on site, and mirrors trends in the upstream facilities. Many constituents in the available data set show concentration trends that align with the trends seen in the Whale Tail Pit and the Whale Tail WRSF Pond. The Whale Tail Attenuation Pond appears to be primarily controlled by the water quality of the Whale Tail Pit.

Although GSP-1 was pumped to the Whale Tail Attenuation Pond in September, the Whale Tail Attenuation Pond does not appear to have been impacted by this water transfer, despite many of the constituents being of higher concentration in GSP-1 than any other source to the Whale Tail Attenuation Pond at the time of the transfer. Exceptions to this are manganese, which increases in concentration in September in the Whale Tail Attenuation Pond, higher than both the Whale Tail Pit and the Whale Tail WRSF, indicating that it is affected by the GSP-1 water transfer. For the remaining constituents, however, there is not a visible increase due solely to the transfer from GSP-1.

As there are only six months of monitoring data at the Whale Tail Attenuation Pond following dewatering of Whale Tail Lake (North Basin), it is anticipated that seasonal variability in concentrations will become more apparent as more data is collected in future years.

Constituent concentrations greater than EQCs include TSS, total aluminum, total arsenic, total chromium, and total iron. Total iron and aluminum concentrations correlate well with TSS concentrations, while total chromium shows a moderate correlation with TSS concentrations, and total arsenic shows little correlation with TSS concentrations, and is more likely controlled by its dissolved form. The remaining constituents remain below their respective EQCs, including total phosphorus, although some concentrations approached the monthly average EQC of 0.3 mg/L, and this constituent should continue to be monitored closely, particularly if TSS concentrations are high.

Figure 6: Monitored concentrations of constituents compared to their respective Effluent Quality Criteria

## 4.0 WATER QUALITY PREDICTIONS

Water quality model results for the Whale Tail WRSF Pond, the Whale Tail Attenuation Pond, the IVR Attenuation Pond, final effluent, and downstream lakes during operations are presented Appendix C. Results for closure and post-closure are also presented in Appendix C for the Whale Tail WRSF Pond, Whale Tail and IVR Pits, and the downstream lakes. Time series figures comparing modelled concentrations to measured data and applicable guidelines are included in the following sections for arsenic and phosphorus as these constituents have historically been the main constituents of concern. The remaining constituents are presented in table format in Appendix C. Modelled water quality constituent predictions represent total constituent concentrations, based on TSS concentrations as described in Section 0, only for the purpose of comparing to monitored data, which is primarily in total concentrations. Once total constituents enter the downstream environment, they are treated conservatively and are only subject to dispersion (i.e., are assumed to remain in suspension and not settle out, be taken up as nutrients, or undergo geochemical reactions that would remove them from the water column).

Predicted concentrations have been compared to specific water quality criteria; constituents that are greater than their applicable criteria are highlighted in Appendix C. On-site water quality predictions are compared to the Water Licence effluent limits (or effluent quality criteria; EQC) (NWB 2020) in operations and closure, while the post-closure predictions are compared to the CEQG-PAL. The downstream receiving environment predictions throughout operations, closure, and post-closure, are also compared to the CEQG-PAL. Note that where applicable, arsenic concentrations are compared to the Site-Specific Water Quality Objective (SSWQO) of 0.025 mg/L in place of the CEQG-PAL.

Predicted concentrations are monthly mean values and are considered to be order-of-magnitude estimates. Actual water quality will largely depend on the mine plan and management practices followed during mining, and on-site conditions related to water movement and chemical loading. In that respect, the extent to which site water quality conditions are influenced by each of the source terms during operations and closure is bound by some uncertainty. Site water quality conditions will be influenced by the degree of contact between water and rock and dissolution kinetics. This will depend largely on climate, particularly the amount of precipitation and evaporation, and the ambient air temperature.

The modelling has assumed that site contact water streams will not be influenced by acid rock drainage inputs. It is assumed that PAG rock management is effective at preventing the development of acid rock drainage by segregating and progressively covering the Whale Tail WRSF with a cover of NPAG/NML waste rock that encompasses the full depth of the anticipated active thaw layer (4.7 m; Golder 2018c), allowing the centre of the pile to freeze. The pH of most contact water streams is therefore expected to be circum-neutral given the low sulphide content and ample carbonate mineral buffering capacity of mine wastes. The rock types that have been identified as PAG demonstrate slow reaction rates in kinetic testing (Golder 2018b).

The input of explosives by-products (i.e., ammonia and nitrate) to site contact water streams has been included in the modelling. The concentration of these nitrogen residuals in site contact water is sensitive to the management of blasting agents during their use. Given the proximity and similarity both in setting and operation of the site to the Meadowbank Mine (similar mining rate, explosives type and explosives usage rate), it was assumed that similar nitrogen and ammonia contents would occur in the waste rock, and open pit drainages.

Water quality predictions for on-site mine contact waters and downstream receiving lakes for the operations, closure, and post-closure phases are discussed in the next sections.

## 4.1 Operations Phase

### 4.1.1 Surface Operations

The modelled constituent concentrations in surface infrastructure contact waters indicate that treatment will likely be necessary through operations. Treatment of all constituents, including arsenic, phosphorus, and TSS, in the discharge was based on an assumed residual mass proportion as untreated site water passes through the AsWTP, and is carried into the receiving environment.

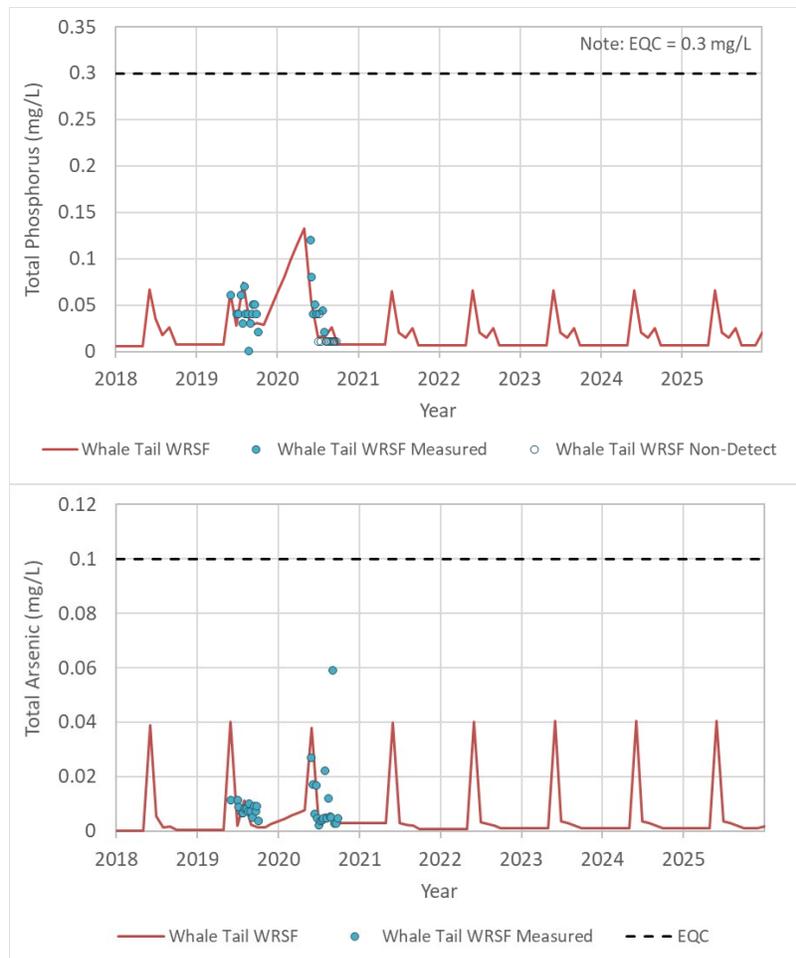

#### 4.1.1.1 *Whale Tail WRSF Pond*

Phosphorus and arsenic concentration in the WRSF Pond are shown in Figure 7. Monitoring data to date supports an increased mass load during high flow periods (freshet) for certain constituents. This is contrary to previous model predictions that showed lower concentrations during freshet, owing to a higher volume of water providing a diluting effect.

Monitoring data support that total phosphorus concentrations are controlled by particulate phosphorus, as there is good agreement between TSS concentration trends and total phosphorus trends. This is also true of arsenic, though not as pronounced. Both total phosphorus and arsenic remain below their respective EQC throughout operations.

Modelled constituents that showed predicted concentrations beyond 2020 that were higher than their respective EQCs were total aluminum, chromium, and iron in June only, when TSS levels are highest. Predicted total iron concentrations also approached the EQC in September. Predicted total mercury, arsenic, cadmium, copper, nickel, phosphorus, lead, zinc, and ammonia did not increase above their respective EQCs in 2021 onwards, though total copper and nickel both showed higher concentrations in 2019 and 2020, respectively; both of these higher concentrations are overpredictions when compared to the monitoring data, which may warrant further investigation.

A subset of constituents, as discussed in Section 3.1, display an increase in concentration over the length of summer in the monitoring. The model was not able to replicate this trend once the waste rock runoff mixed with natural runoff and direct precipitation, and further investigation is warranted as more monitoring data is collected in future years.

**Figure 7: Projected total phosphorus (a) and total arsenic (b) concentrations for the Whale Tail WRSF Pond during operations. Open circles represent non-detected values at the detection limit for measured data.**

### 4.1.1.2 Whale Tail Attenuation Pond

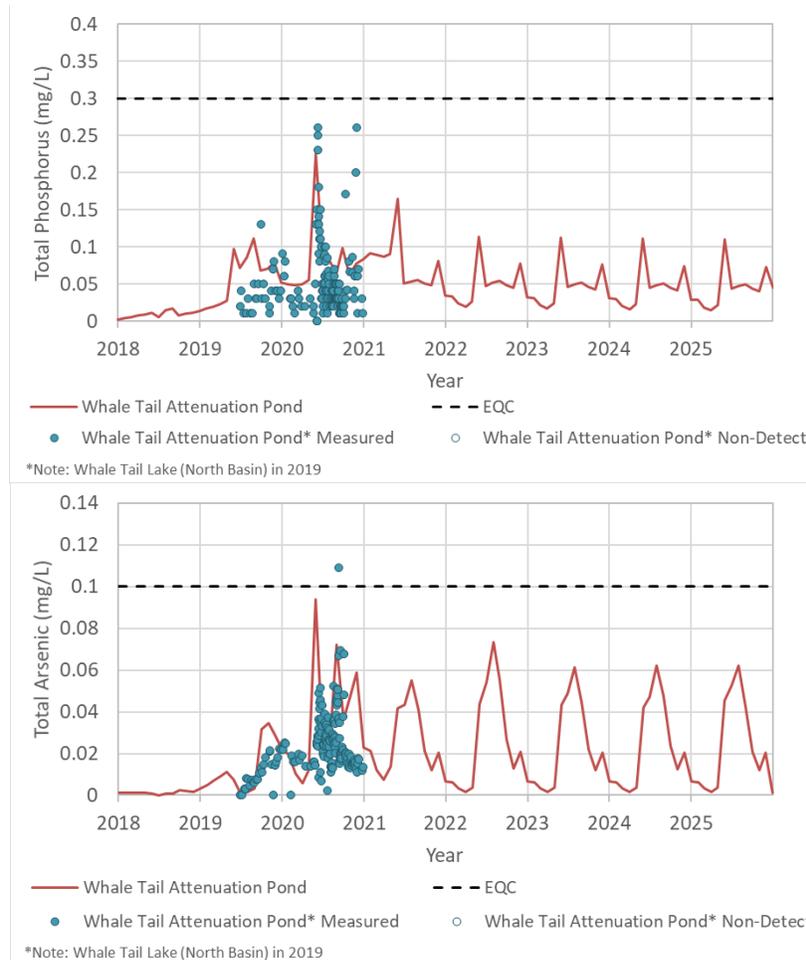

The mostly dewatered Whale Tail Attenuation Pond was used in 2019 to collect seepage water through the Whale Tail Dike; based on monitoring data this water discharged directly to the environment. In 2020 the Whale Tail Attenuation Pond was functional; collected site contact water was sent through the AsWTP and discharged to Whale Tail Lake (South Basin) and Mammoth Lake.

Generally, predicted concentrations in the Whale Tail Attenuation Pond increase in 2020, but decrease slightly and become stable for the remainder of operations. This trend occurs because in June 2021, when contact water is directed to the IVR Attenuation Pond, and the Whale Tail Attenuation Pond only continues receiving runoff from its immediate catchment area, and seepage through the Whale Tail Dike. Of those constituents with an applicable EQC, a slight increase in total arsenic, mercury, and nickel concentrations can be seen in 2022 relative to 2021; this is due to an increase of ore stockpile tonnage placed within the catchment area of the Whale Tail Attenuation Pond in that year.

The modelled Whale Tail Attenuation Pond arsenic concentrations increase from June through August and decrease again from September through the winter months, when there is no site runoff contact water. In the winter months, there is proportionally more contribution of groundwater and drilling water to the pit sumps, which have lower arsenic concentrations.

Predicted total phosphorus concentrations show a higher degree of variability throughout the year, and are affected both by the variation in TSS concentrations (higher in June, for example), groundwater inflows, and the STP effluent. As with arsenic, the predicted total phosphorus concentrations show a reduction in 2021; this is due the majority of contact water and STP effluent being directed to the IVR Attenuation Pond at that time, which reduces the loading to the Whale Tail Attenuation Pond.

Modelled constituents that showed concentrations consistently above their respective EQCs were total aluminum, iron, and chromium. Total mercury, cadmium, copper, nickel, lead, zinc, and ammonia remained below their respective EQCs.

**Figure 8: Projected total phosphorus (a) and total arsenic (b) concentrations for the Whale Tail Attenuation Pond during operations.**

### 4.1.1.3 *IVR Attenuation Pond*

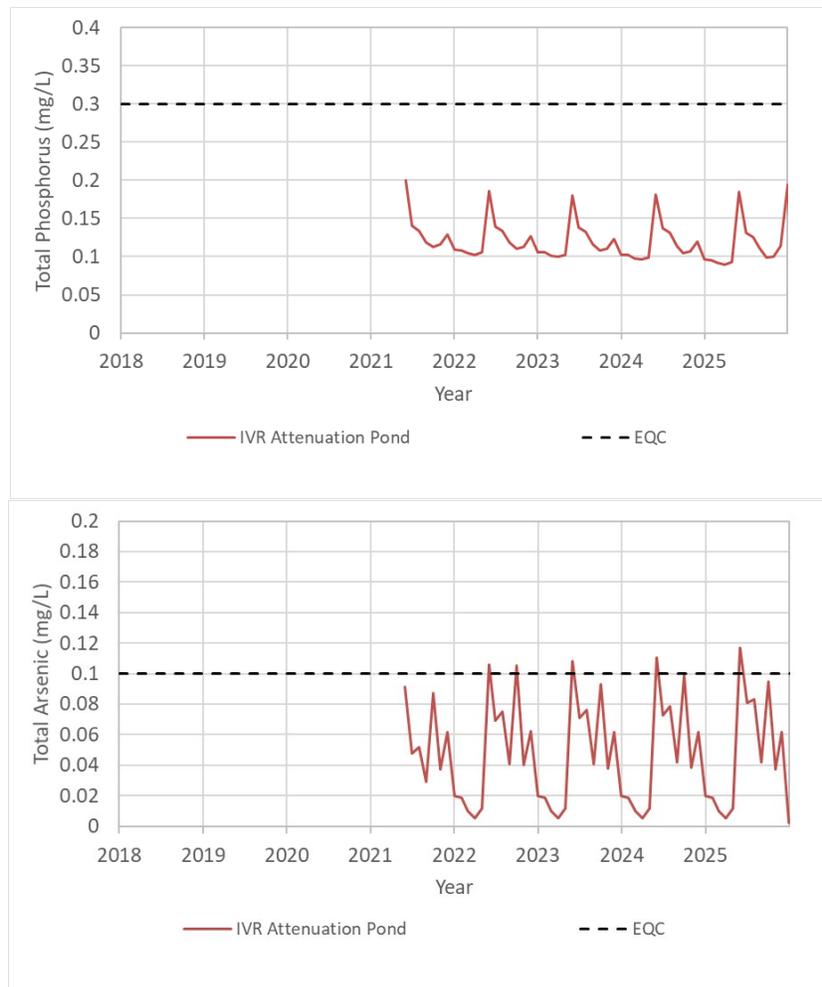

The IVR Attenuation Pond will collect all contact water on site and discharge to either Mammoth Lake or Whale Tail Lake (South Basin) via the AsWTP. As the IVR Attenuation Pond is anticipated to come online for freshet of 2021, no monitoring data exists and therefore the updates developed for the Whale Tail Attenuation Pond was applied. Total concentrations were calculated using the TSS concentrations in the Whale Tail Attenuation Pond as a proxy; this is considered conservative as the operational elevation of the IVR Attenuation Pond will result in a larger volume than the maintained volume of the Whale Tail Attenuation Pond, which will allow for more settling of particulate matter.

Predicted total arsenic concentrations show a large amount of variability (Figure 9), but are consistently at or above the EQC, particularly in June and October. Concentrations generally decrease during the winter months, and increase during the summer months, due to an increase in site runoff resulting in contact water.

Concentrations show an increase from 2021 to 2022, reflective of the opening of the IVR Pit to its maximum footprint through that time period and an increased load from ore stockpiles. These predicted concentrations indicate that treatment for arsenic will be required for the remainder of operations.

Predicted total phosphorus concentrations show a seasonal increase in June, reflective of higher TSS concentrations. Concentrations decrease slightly but generally remain stable and within the range predicted for the Whale Tail Attenuation Pond for 2020. Predicted concentrations remain below the site EQC for the duration of operations, though daily variability in the monitoring data shows concentrations approaching the EQC and supports the continuation of treatment prior to discharge.

Other modelled constituents that showed concentrations consistently above their respective EQCs were total aluminum and iron. Total mercury, cadmium, chromium, copper, nickel, lead, zinc, and ammonia remained below their respective EQCs.

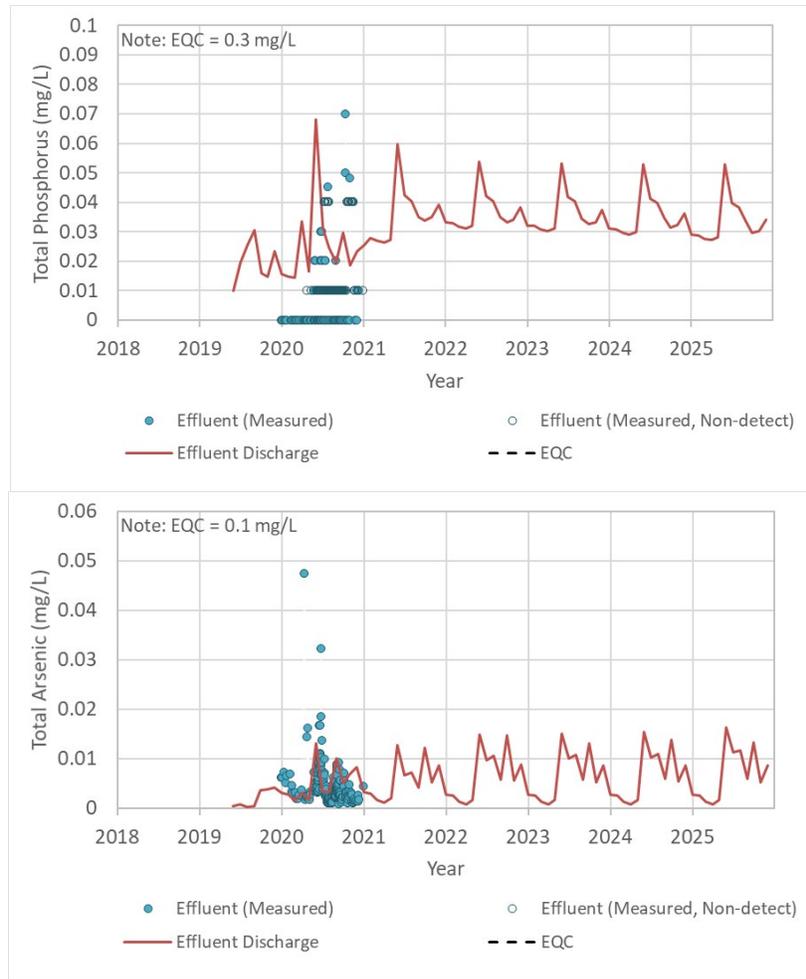

**Figure 9: Projected total phosphorus (a) and total arsenic (b) concentrations for the IVR Attenuation Pond during operations.**

#### 4.1.1.4 AsWTP Effluent Discharge

The AsWTP effluent (Figure 10) is required to meet licence limits (NWB 2020). As discussed in Section 2.1.1, a treatment efficiency, based on differences in monitored concentrations in the Whale Tail Attenuation Pond and the AsWTP Effluent, was used to approximate treated effluent concentrations from the predicted water quality in the Whale Tail Attenuation Pond. These treatment efficiencies were applied through operations to all effluent, regardless of destination.

All modelled constituents that are regulated under the Water Licence A (NWB 2020) are predicted to be less than their respective effluent limits when passed through the AsWTP. As the predicted concentrations are monthly average concentrations, they do not show the daily variability that may occur; however, there were no exceedances in the monitoring data of maximum grab sample effluent limits.

**Figure 10: Projected total phosphorus (a) and total arsenic (b) concentrations for the treated AsWTP effluent discharge during operations. Open circles represent non-detected values at the detection limit for measured data.**

### 4.1.2 Receiving Environment and Downstream Lakes

Results presented for the receiving environment and downstream lakes assume fully mixed conditions (as predicted for Mammoth Lake (Golder 2019c)), where the effluent and downstream lake overflow volumes and associated chemical loads are assumed to be transferred instantaneously. It is expected that changes in concentrations in the downstream lakes due to effluent discharge will show a lag, which will increase with distance from the discharge location. It should also be noted that predicted total concentrations in the downstream lakes do not account for any settling within the water column; the particulate fraction of total concentrations is assumed to remain suspended as it travels through the downstream pathways.

During the operations phase, treated water is discharged from the AsWTP, through a diffuser, to Mammoth Lake through the summer months and to Whale Tail Lake (South Basin) in the winter months.

Model results for the receiving and downstream environment were compared to the CEQG-PAL. Generally, concentrations are often over-predicted in Mammoth Lake and Whale Tail Lake (South Basin), despite fairly good alignment of predicted concentrations with monitored concentrations in the treated effluent. As these discrepancies occur to a larger degree through the winter months, it is likely that the coarse assumptions surrounding ice formation (instantaneous formation of 2 m of ice in the fall and melting over the month of June) are overly conservative. Ice records on Mammoth Lake and Whale Tail Lake (South Basin) support the use of 2 m

of ice formation; however, in reality the ice may take months to form, which could affect the evolution of water quality through the winter months. Mammoth Lake in particular is sensitive to ice formation as it has limited volume and depth, which may exacerbate the discrepancies between predicted and monitored concentrations. It is also possible that cryoconcentration is not occurring to the extent previously assumed (i.e., completely clean ice), or that some constituents may be incorporated into the ice more readily than others. Most likely it is a combination of gradual ice formation and particle settling that affect these discrepancies. The major ions, in particular, show better alignment with seasonal concentrations, but metals do not align as well.

Many constituents show an increase in predicted concentrations between 2020 and 2021 in Mammoth Lake as treated effluent is directed there annually during the summer months, with concentrations generally stabilizing or even decreasing between 2021 and 2025. The exceptions to this trend are total mercury, silver, arsenic, copper, nickel, thallium, and nitrate. Modelled constituents that are predicting exceedances of CEQG-PAL in Mammoth Lake are:

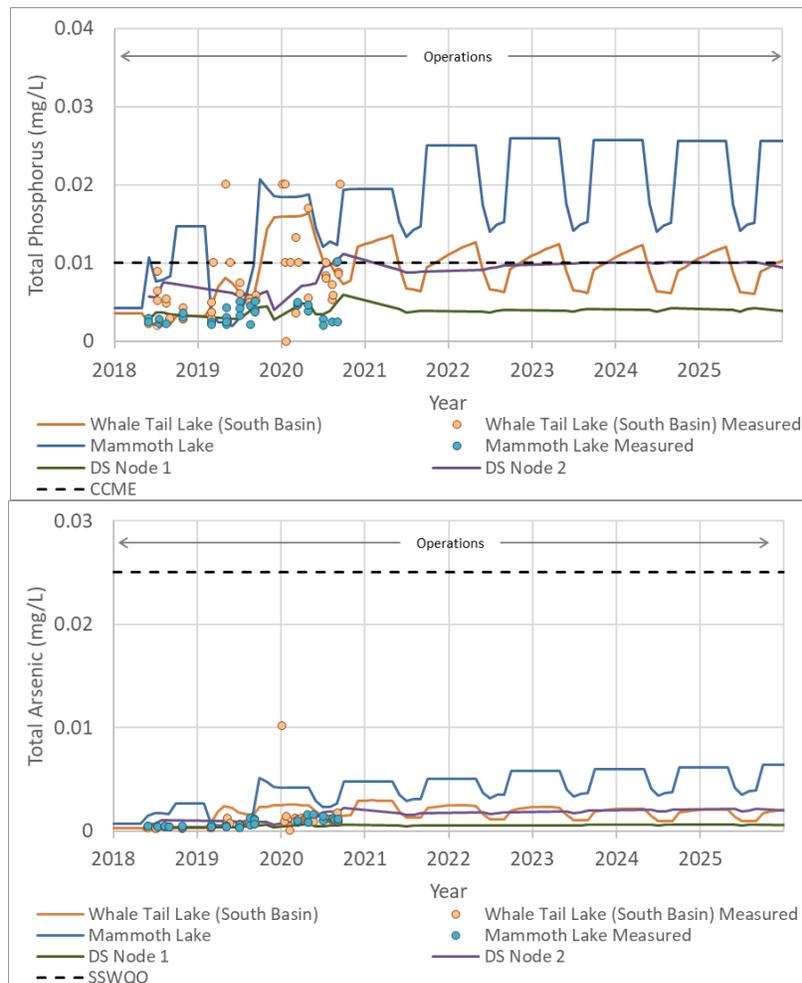

- Total aluminum: The exceedances are predicted to have previously occurred (i.e., in 2020), which measured data has demonstrated did not occur. Therefore, the model is over-predicting total aluminum concentrations in 2020 and is likely continuing throughout the modelled period.
- Total copper: The exceedances are predicted to occur only under ice, and there are no exceedances in the summer months. Further, the model is over-predicting total copper concentrations in 2020 and is likely continuing throughout the modelled period.
- Total iron: The exceedances are predicted to occur only under ice, and there are no exceedances in the summer months. Further, the model is over-predicting total iron in 2020 and is likely continuing throughout the modelled period.
- Total phosphorus: Predicted concentrations fall within the mesotrophic range (0.01 – 0.02 mg/L) in the summer months and fall within the meso-eutrophic range (0.02 – 0.035 mg/L) under ice. This is consistent with predictions provided from previous iterations. Concentrations are not predicted to attain levels within the eutrophic range (0.035 – 0.1 mg/L) or higher. Further, the model is generally overpredicting total phosphorus; it does not account for settling of particulate matter nor the uptake of phosphorus as a nutrient, which may result in some reduction in the concentrations in the water.
- Nitrate: The exceedances are predicted to occur only under ice, and there are no exceedances in the summer months.

Treated effluent is discharged to Whale Tail Lake (South Basin) in the winter months. Many constituents show an increase in predicted concentrations between 2019 and 2020 in Whale Tail Lake (South Basin), however predicted concentrations decrease throughout operations as the low flow winter discharge does not contribute enough mass to increase concentrations. Like Mammoth Lake, predicted concentrations in Whale Tail Lake (South Basin) are generally overpredicted. Some constituents are not well aligned for late-2019, and some constituents are slightly underpredicted in 2020. These include total nickel and lead (though data is limited as it is often below the detection limit).

Predicted concentrations of all constituents that have applicable CEQG-PAL (or SSWQO in the case of total arsenic) do not exceed their respective guidelines. Predicted concentrations of total phosphorus are within the oligotrophic range (0.004 – 0.01 mg/L) in the summer months, and the mesotrophic range (0.01 – 0.02 mg/L) in the winter months.

As discussed above, modelled constituents that have applicable CEQG-PAL (or SSWQO in the case of total arsenic) often are overpredicted by the model; however, both the monitored data and the model predictions remain well below the respective CEQG-PAL for the constituents not discussed above.

With respect to the furthest downstream model nodes, which are inlets to Lake DS1 (see Figure 2), no exceedances are propagated to Downstream Node 1 (DS1) or 2 (DS2). Predicted total phosphorus remains in the ultra-oligotrophic (< 0.004 mg/L) and oligotrophic ranges in DS1, and the oligotrophic and mesotrophic ranges in DS2.

**Figure 11: Projected total phosphorus (a) and total arsenic (b) concentrations for the receiving and downstream environment during operations. Open circles represent non-detected values at the detection limit in measured data.**

## 4.2 Closure

### 4.2.1 Surface Operations

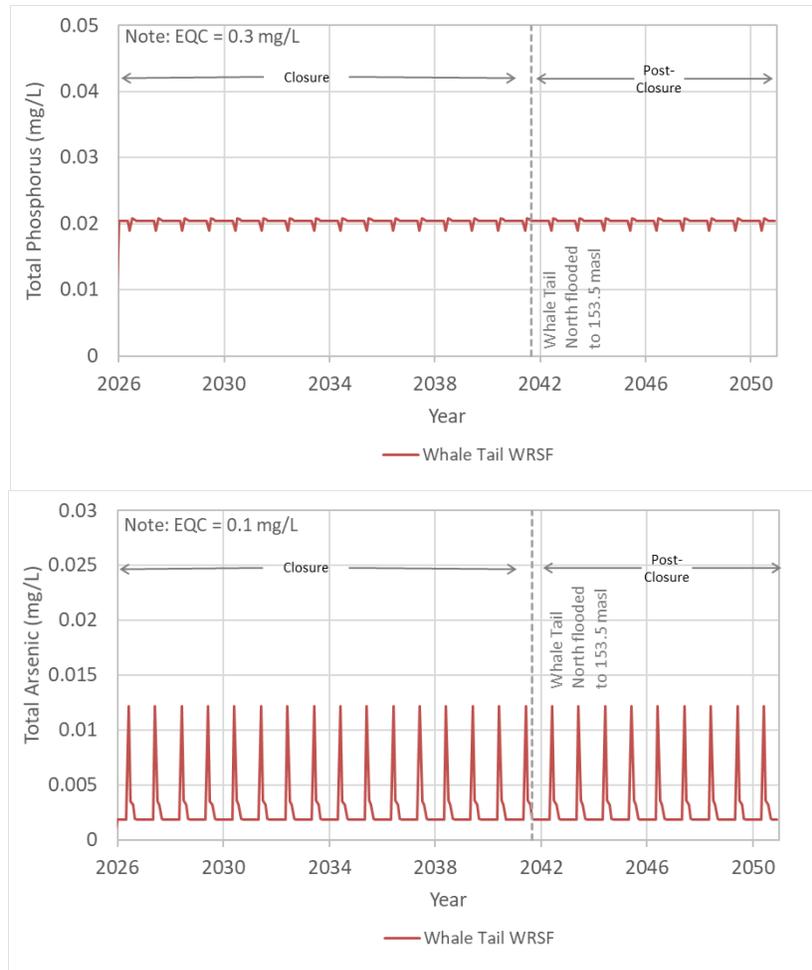

In early closure, all site contact water is transferred into the IVR Pit, which spills into Whale Tail Pit, until the pit lake is flooded to 153.5 masl (2041). During this time, site contact water quality improves as a result of closure activities including the removal of stockpiles with the eventual reclamation of all constructed pads.

As the pit lake is reflooding, a comprehensive water quality monitoring program may be undertaken based on monitoring data to ensure that both physical and chemical stability are achieved within the pit by the time it is fully flooded. The results from the monitoring program will be compared to model predictions, which in turn will inform the reflooding strategy if required, which may be adapted to achieve closure objectives. The closure objective is that pit lake water will meet water quality objectives concurrently with completed reflooding so that lake reconnection can occur once the pit lake reaches its full supply level.

#### *Whale Tail WRSF*

The WRSF contact water quality is predicted to show an improvement in closure due to the application of 10 mg/L of TSS, representing the covering of the Whale Tail WRSF (Figure 12). Total arsenic and phosphorus concentrations show seasonal variations based on the updates applied. Total phosphorus shows higher concentrations in June, with a decreasing trend through the summer. Total arsenic shows lower concentrations in June, with slightly higher concentrations in July and August. Both total arsenic and total phosphorus remain below their respective EQCs in the WRSF runoff. Basal seepage is not anticipated to occur, as per the results of the hydrological modelling of the WRSF (Appendix E of Golder 2019b).

Total aluminum, chromium, and iron concentrations are greater than the EQCs in June only, when TSS levels are also highest; all other modelled constituents with EQCs show no exceedances.

**Figure 12: Projected total phosphorus (a) and total arsenic (b) concentrations for the Whale Tail WRSF pond in closure and post-closure.**

**IVR Pit**

At the start of closure, IVR Pit receives a large volume of fresh water for flooding that is anticipated to input little to no loading of arsenic or any other constituent. The flooding therefore results in an improvement to water quality in the pit as it floods during closure (i.e., predictions of progressively lower constituent concentrations in the flooding lake as the pit fills).

Water quality in the IVR Pit (Figure 13) is predicted to have some elevated constituent concentrations initially during flooding. This results from the comparatively large mass load from the pit benches and floors compared to the relatively small volume of water present in the pit sump at the onset of flooding. This water remains in the pit and water quality improves with flooding inflows as the exposed pit wall surface area decreases with pumped inflows from Whale Tail (South Basin) and the contribution of natural runoff from the drainage basin. Total arsenic concentrations are predicted to decrease below the SSWQO within the first year of closure and continue to decrease into post-closure. Predicted total phosphorus shows the same decreasing trend and remains in the oligotrophic range throughout all of closure and post-closure.

No concentrations greater than the CEQG-PAL (chronic) were predicted for chloride, fluoride, nitrate, or total concentrations of mercury, silver, aluminum, boron, cadmium, copper, iron, molybdenum, nickel, lead, selenium, thallium, uranium, or zinc.

### **Whale Tail Pit**

In closure, the primary sources of filling Whale Tail Pit are the overflow from IVR Pit and the overflow from the Whale Tail Attenuation Pond. Similar to the IVR Pit, the Whale Tail Pit (Figure 13) is predicted to have some elevated constituent concentrations initially during flooding, due to an initial mass load from the pit benches and floors compared to the small volume of water present. Throughout closure, however, the flooding results in an improvement to water quality in the pit as the IVR Pit improves in water quality. The Whale Tail Attenuation Pond is a source of some elevated concentrations to the Whale Tail Pit, but the flow is much less than from the IVR Pit overflow.

Total arsenic concentrations are predicted to decrease below the SSWQO prior to the completion of flooding and continue to decrease into post-closure. Total phosphorus concentrations decrease to within the oligotrophic range within a few years of post-closure.

No concentrations greater than the CEQG-PAL (chronic) were predicted for chloride, fluoride, nitrate, or total concentrations of mercury, silver, aluminum, boron, cadmium, copper, iron, molybdenum, nickel, lead, selenium, thallium, uranium, or zinc.

### **Whale Tail Attenuation Pond**

Total phosphorus concentrations in the flooded Whale Tail Attenuation Pond show a decrease to the oligotrophic range between 2040 and 2042, as it merges with the flooded Whale Tail Pit and IVR Pit and begins receiving inflows from Whale Tail Lake (South Basin) following flooding up to 153.5 masl. Total arsenic is predicted to be below the SSWQO at the start of closure. Total copper is predicted to reach the CEQG-PAL during closure, but concentrations decrease as the Whale Tail Attenuation Pond merges with the pit lake.

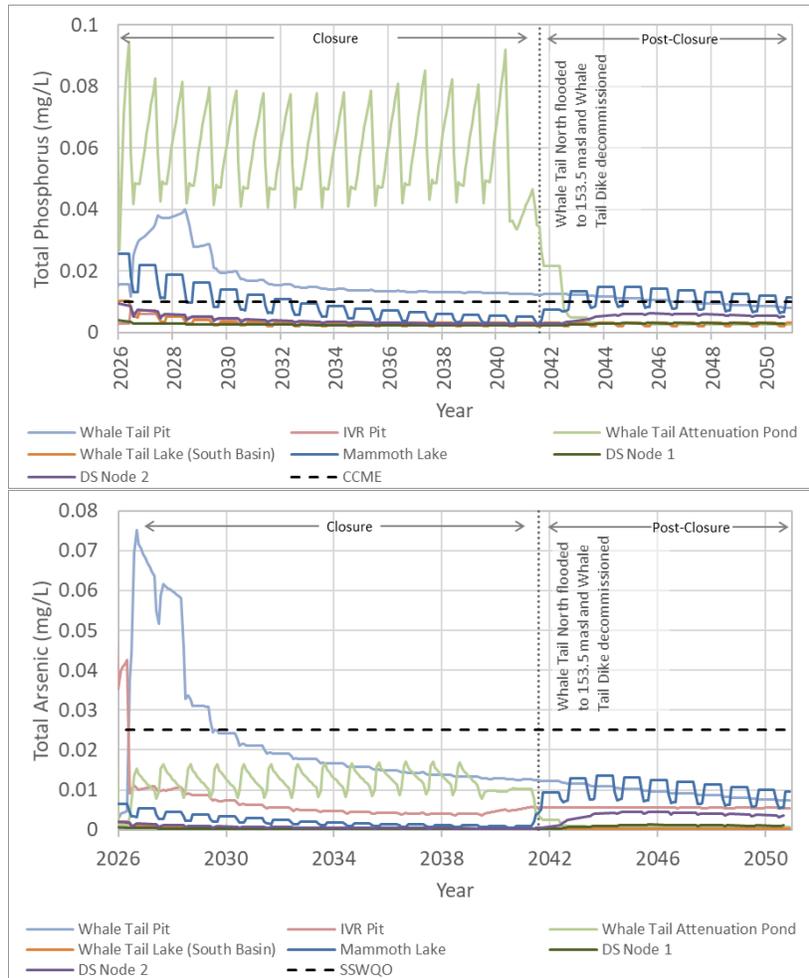

No concentrations greater than the CEQG-PAL (chronic) were predicted for chloride, fluoride, nitrate, or total concentrations of mercury, silver, aluminum, boron, cadmium, iron, molybdenum, nickel, lead, selenium, thallium, uranium or zinc..

## **4.2.2 Receiving Environment and Downstream Lakes**

During flooding of the Whale Tail Pit Lake, site discharges to the receiving environment cease and are redirected to the IVR open pit until a flooded elevation of 153.5 masl is reached (predicted to occur in 2041). Whale Tail Lake (South Basin) is drawn down to 153.5 masl and all flow through the Whale Tail Lake (South Basin) Diversion Channel to Mammoth Lake ceases. During active flooding, Mammoth Lake and all downstream lakes trend towards baseline conditions, since only natural runoff enters their systems. For the majority of the modelled constituents with applicable CEQG-PAL, this results in a steady decrease in concentrations. For total boron and lead concentrations increase slightly as baseline concentrations are above the predicted concentrations at the end of operations. Water quality constituent concentrations progressively decrease through the downstream environment during this time (Figure 13).

Phosphorus concentrations decrease to the oligotrophic range in open water conditions within a few years after the start of closure. Under-ice concentrations decrease to oligotrophic levels in 2033, approximately 8 years into closure. Under ice and open water total arsenic concentrations are predicted to be below the SSWQO in Mammoth Lake from the beginning of closure. Predicted total copper, iron, zinc, and nitrate concentrations exceed the CEQG-PAL under ice for the first couple of years into closure only.

No concentrations greater than the CEQG-PAL were predicted for chloride, fluoride, or for total concentrations of mercury, silver, aluminum, boron, cadmium, molybdenum, nickel, lead, selenium, thallium, or uranium.

**Figure 13: Projected total phosphorus (a) and total arsenic (b) concentrations for the Whale Tail Pit, the IVR Pit, the Whale Tail Attenuation Pond, and the receiving environment during closure and post-closure.**

### 4.3 Post-Closure

Post-closure occurs when the Whale Tail Pit lake is fully flooded and water meets closure water quality objectives, which is predicted to occur prior the completion of flooding. At that time, both the Mammoth Dike and the Whale Tail Dike are decommissioned, the Whale Tail Lake North and South Basins are reconnected, and water naturally flows over the Mammoth sill into Mammoth Lake from the Whale Tail Lake (North Basin). Mammoth Lake also receives runoff directly from the Whale Tail WRSF.

#### Pit Lake

Concentrations of all water quality constituents throughout the pit lake are predicted to remain below receiving water quality objectives in post-closure. The Whale Tail Pit, IVR Pit, and the Whale Tail Attenuation Pond are connected at the surface and water is exchanged between them.

### **Downstream Water Quality**

Water quality in Mammoth Lake and the downstream lakes show an initial increase in some predicted concentrations at the start of post-closure; this is due to a large volume of water flowing from the flooded pit lake, which has higher concentrations than Mammoth Lake at that point in time (for example, total arsenic). All predicted concentrations are predicted to meet the CEQG-PAL. Predicted total phosphorus concentrations increase slightly but remain within the oligotrophic range in open water conditions and begin decreasing again within a couple of years of post-closure. Predicted total arsenic remains below the SSWQO in post-closure, and continue to trend to conditions similar to baseline.

## **5.0 STUDY LIMITATIONS**

Golder Associates Ltd. (Golder) has prepared this document in a manner consistent with that level of care and skill ordinarily exercised by members of the engineering and science professions currently practicing under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this document. **Table B6: Exposed pit wall proportions (%) by lithology for Whale Tail and IVR Pits**

Lithology / Material Type	Whale Tail Pit	IVR Pit
Gabbro (I3)	0	22
Chert (S10) <sup>1</sup>	8.1	2.0
Greywacke North (S3N)	17	6.0
Central Greywacke (S3C)	7.3	1.8
Iron Formation (SE9)	5.7	0
Ultramafic (0b)	17	55
Ultramafic (0a) <sup>2</sup>	5.8	14
Basalt (1b)	6.6	0
Overburden <sup>3</sup>	0	0
Diorite (8b)	16	0
South Greywacke (S3S)	16	0

**Notes:**

1. Includes Chert Central (S10C) and Chert zone R (S10R)
2. Includes Non-Defined Waste
3. In the pit wall, the overburden is pushed back from the pit wall and does not contribute chemical load to the runoff flowing into the Whale Tail Pit.

**Table B7: Pit Wall Areas in m<sup>2</sup> (year end) used to Calculate Mass Loading Rates. Values are linearly interpolated in the model**

Year	Quarry 1	Starter Pit	Whale Tail Pit	IVR Pit
2017	28,077	-	-	-
2018	45,579 <sup>1</sup>	52,387	-	-
2019	-	132,990 <sup>2</sup>	-	-
2020	-	-	563,667	77,773
2021	-	-	565,171	174,691
2022	-	-	565,171	355,467
2023	-	-	565,171	355,495
2024	-	-	565,171	355,495
2025	-	-	565,171	355,747

**Notes:**

1. Ultimate area achieved by mid-July 2018.
2. Becomes Whale Tail Pit when Whale Tail Lake (North Basin) is dewatered.

## **B2.0 LOADING RATES AND CONCENTRATIONS**

### **B2.1 Exposed Rock in Pit Walls, WRSFs, Pads, and Stockpiles**

Table B8 through Table B13 summarizes the water quality related input parameters used in the water quality model. Loading rates are calculated for waste rock (based on large column leaching tests<sup>1</sup>), ore (based on humidity cell tests [HCT] leach), and overburden, esker material, and lakebed sediments (based on shake flask extraction [SFE] leach test results). All leach tests (large columns, HCTs, SFE) are described in the Geochemistry Report (Golder 2018a). Loading rates and concentrations (Appendix A) were normalized and adjusted to field conditions in the model, and further scaling factors were applied as per Table B8.

The weekly analytical results were used to calculate an average weekly leaching rate per unit mass for each constituent and each leaching cell or column as reported in the Geochemistry Report. Laboratory leaching rates are more aggressive than what would be observed in the field. This is usually a function of two factors:

- The higher liquid to solid ratios used in testing compared to much drier site conditions maximizes the amount of material that interacts with the liquid; and,
- Laboratory tests carried out at room temperature accelerates oxidation rates. Laboratory temperature is not representative of colder temperature at the project site, which will slow the oxidation rates based on chemical principles and is documented at other northern sites (Davé and Clulow 1996; Davé and Blanchette 1999).

The laboratory-derived leaching rates were applied as a monthly loading rate in the model in consideration of the drier climate at site where much less precipitation falls on a unit surface area than in the laboratory leaching column. One weekly leaching cycle in the laboratory represents the volume of water that is received in 2 to 3 months of exposure in the pile for the same unit surface area<sup>2</sup>. The laboratory leaching rate is repeated 4 times in one month; therefore, time in the laboratory test does not correspond to mine waste exposure time in the field. Based on the liquid to solid ratio of one laboratory leaching cycle relative to the monthly average precipitation, the chemical load associated with one laboratory leaching cycle was conservatively assumed to represent the load released from one month of precipitation in the field. Loading rates were calculated from the large column leachate water quality data as follows:

$$\text{Loading Rate} \left( \frac{\text{mg}}{\text{kg}} \right) = \text{average of weekly rate, as: } \frac{\left( \text{concentration} \left( \frac{\text{mg}}{\text{L}} \right) \times \text{leachate volume (L)} \right)}{\left( \text{mass of charge material (kg)} \right)}$$

As the Whale Tail and IVR Pits become flooded, mass is expected to be released from the pit benches and pit floors under water. This process results from the mobilisation of sulphur salts created upon exposure of the rock to air prior to flooding. Submergence is expected to stop oxidation but will allow salts to dissolve. Thus, the amount of salts available to be released from of the pit benches and floors will be a finite source. To capture the effects on water quality of the slow release of these stored salts, a finite release of mass from the pit benches and floors was applied in the model (Golder 2018b). Following the depletion of the mass due to remobilisation into the

<sup>1</sup> With the exception of the diorite unit, which is based on humidity cell test results

<sup>2</sup> Based on an average climate year, total precipitations (rain and snow) for frost-free months of June to September when rock storage facility contact water may be released. This applies to the surface area of all mine wastes: rock storage facilities, pads and stockpiles.

flooded pits, mass release from the pit benches and floors was assumed to be driven by equilibrium processes with groundwater concentrations.

Mass release rates from the submerged pit benches and floors were derived from diffusion modeling described in Golder (2018b). A mass release rate was estimated for all lithologies; however, only the komatiite, iron formation, and greywacke rocks provide mass release upon submersion; all other lithologies provide negligible mass release upon submersion.

## **B2.2 Overburden, Esker Material, and Exposed Lakebed Sediment**

No kinetic leaching tests were carried out on overburden, esker material, or lakebed sediments. To calculate average leaching rates per unit mass of material, SFE static leaching test results were used as described in the Geochemistry Report. SFE static leaching tests are more aggressive than leaching rates in the field, as material is shaken for 24 hours in water with a liquid to solid ratio of 4:1. This results in a higher release of constituents per unit mass of testing material than would be observed in the field. Loading rates were calculated from the SFE data as follows:

$$\text{Loading Rate } \left( \frac{mg}{kg} \right) = \left\{ \frac{\left( \text{concentration } \left( \frac{mg}{L} \right) \times \text{leachate volume } (L) \right)}{\left( \text{mass of charge material } (kg) \right)} \right\}$$

Overburden and esker material will be piled and exposed to precipitation. As such, a conservative approach of applying the loading rates on a monthly basis was used. Scaling factors were applied as per Table B8 and Table B11.

A different approach was used for the lakebed sediment, as they will remain *in situ* and undisturbed. According to the annual net runoff depth per unit area used in the model, and under the assumption of a 5 cm interaction depth of lakebed sediments, the liquid to solid ratio for lakebed sediments on site is calculated to be approximately 2:1. When considering the entire volume of natural runoff within the catchment plus runoff over the exposed lakebed sediments, this ratio becomes approximately 4:1, which is consistent with the water to rock ratio of the SFE test. Therefore, the average loading rate was assumed to be released on an annual basis, and reports to runoff, which occurs entirely between June and September. Scaling factors were applied as per Table B11.

**Table B11: Inputs and Assumptions for Other Loadings Sources**

Facility	Property	Input / Assumption	Rational	Reference	Operations	Closure	Post-Closure
Attenuation Pond Exposed Lakebed Sediments	Runoff over lakebed sediments	Input as a loading. Assumed to be the loading rate equivalent to one full year of precipitation but released entirely over the open water season (June through September, a total of 122 days).	Whale Tail Lake (North Basin) dewatering will expose lakebed sediment area. Lakebeds will be submerged once Whale Tail Lake (North Basin) is full in closure.  Water-rock ratios of the geochemical testing (SFE tests) indicates that applying the loading as an annual rate is conservative, based on the average annual precipitation (Appendix B, Section B2.2).	Appendix A	X	X	
	Interaction depth of runoff water on lakebed sediments	5 cm	Geochemical testing done on 5 cm of material. Lakebed sediments consist of silty clays that are hard packed and will provide a relatively impermeable surface.		X		
	Density of lakebed sediments	1.5 g/cm <sup>3</sup>	Lakebed sediments consist primarily of silty clay.	USDA estimate of moist bulk density by texture (USDA, 2019)	X		
	Temperature effect	<ul style="list-style-type: none"> <li>■ 0.5 for July and August</li> <li>■ 0.25 for June and September</li> <li>■ 0 for October to May</li> </ul>	Loading rates are halved for every 10°C decrease in temperature from 25°C, based on monthly average temperatures. Factor is 0 in winter months as average monthly temperatures are below 0°C	Diavik (1998); Davé and Clulow (1996); Davé and Blanchette (1999)	X		
Attenuation Pond Natural Runoff	Runoff from natural watershed areas	If lakebed sediments are exposed, assumed to not contain mass as it will acquire mass from lakebed sediments. If lakebed sediments are not exposed, it is represented by natural runoff water quality.	The runoff flow from the natural areas will flow over the exposed lakebed sediments and acquire mass. This is anticipated to be a greater mass than natural runoff water quality.	Appendix A	X	X	X

## **B4.0 GEOCHEMICAL CONTROLS ON WATER QUALITY**

### **B4.1 Solubility Limits**

Evaporation and recirculation of water increase concentrations of some constituents to beyond their solubility limits. Geochemical modelling was carried out on the modelled water quality of Whale Tail WRSF Contact Water Collection System, Whale Tail Attenuation Pond water, and Whale Tail Pit sump water to define the likely upper concentration limit for constituents controlled by solubility for the Approved Project site water quality model. The same solubility limits were applied to the current model as pH and oxidizing conditions are expected to be similar for all inflows, assuming acid rock drainage (ARD) is prevented from PAG rock.

The United States Geological Society mass transfer and speciation modelling code PhreeqC (Version 2.15.0) (Parkhurst and Appelo 1999) was used for this purpose. PhreeqC calculates aqueous speciation and solubility indices of solutions using the thermodynamic equations of mineral phases, assuming equilibrium conditions between mineral and soluble phases. The user specifies credible mineral phases that are allowed to precipitate. PhreeqC returns concentrations remaining after precipitation of the specified mineral phases and solubility indices for all mineral phases in the PhreeqC database. This code is widely used and accepted by the scientific and regulatory community.

GoldSim water quality results consisting of the water quality output from distinct time-steps for each of the stated ponds were used as input to PhreeqC. Pond waters were assumed to have a pH of 7 based on observed pH ranges in kinetic testing (Golder 2018a), and to be fully oxidizing.

The PhreeqC results identified iron and aluminum as being supersaturated in predicted water quality, and subject to solubility control through the precipitation of diaspore [AlO(OH)], and ferrihydrite in the expected neutral pH and oxidizing conditions in the ponds. The precipitates formed were assumed to be permanently removed from the mass balance and the remaining aqueous concentration of iron and aluminum were considered to represent maximum concentrations in these ponds at any time. These solubility limits were applied to aluminum and iron as summarized in Table B12 and were hardwired into the GoldSim model as upper concentration limits for these constituents in water. The GoldSim model was then re-run with these fixed upper concentration limits.

**Table B12: Solubility Limits Applied in the Water Quality Model**

Constituent	Unit	Whale Tail Waste Rock Storage Facility Pond	Whale Tail Pit Sump	Whale Tail Attenuation Pond
Aluminum	mg/L	0.0003	0.0002	0.0001
Iron	mg/L	0.06	0.7	0.3

**Notes:** mg/L = milligrams per litre

## **B4.2 Effect of Total Suspended Solids on Total Constituent Concentrations**

Though Total Suspended Solids (TSS) are not explicitly modelled, concentrations of TSS are assumed for sources into Mammoth and Whale Tail Lake (South Basin) and carried downstream conservatively (i.e., does not settle out but is subject to dilution effects). Using the assumed TSS concentrations, based on monitoring data and as described in Section 2.1.1.1 of the report, total metal concentrations for Project on-site facilities and discharges were estimated by adding a calculated particulate fraction to the dissolved concentration results from the model. Particulate fractions for the relevant constituents were based on solid phase geochemistry of each rock type and the proportion of each rock type in the final waste rock mass.

Total concentrations could differ from predicted if TSS with variability of TSS concentrations in the Expansion Project or if the TSS has a different chemical composition.

During operations, the addition of the particulate fraction did not produce any substantial change from the dissolved concentrations for most constituents except aluminum, chromium, and iron, and phosphorus, which showed a substantial increase in total concentration. This is expected for aluminum and iron as they were assumed to constitute the bulk of the chemical make up of TSS. Any presence of total aluminum or iron in effluent would be attributed to particulates rather than the dissolved phase given the anticipated neutral pH and oxidative environment of all site surface waters. Calcium and magnesium also comprise an important part of the suspended solids chemical composition, but their concentration is predicted to be elevated such that the additional contribution from TSS does not cause significant change.

In closure and post-closure, it was assumed that TSS concentrations in the flooded pit lake would drop to approximately 1 mg/L, as particulate matter settles out of the water column. This is consistent with baseline TSS values from the area. An assumed TSS concentration of 10 mg/L was applied to runoff that enters Mammoth Lake from the Whale Tail WRSF Pond in post-closure. This is consistent with baseline stream values as well as channel values at Meadowbank (Golder 2019b). Table B13 presents modelled particulate concentrations for TSS concentrations of 1 mg/L, 7.5 mg/L, 10 mg/L, and 15 mg/L. Total concentrations are calculated by multiplying the values for 1 mg/L of TSS by the assumed TSS concentration and adding these particulate concentrations. This is applied to the predicted dissolved concentrations for any water being discharged, as well as the Whale Tail Attenuation Pond, Whale Tail Pit, IVR Pit, and Whale Tail WRSF in closure and post-closure.

This sensitivity analysis suggests that the presence of suspended solids to a maximum concentration of 15 mg/L is not likely to affect trace constituent concentrations such as arsenic because the concentration in the original mass is too low to result in a significant change in constituent concentrations. Conversely, rock forming elements such as iron, aluminum, potassium, magnesium and calcium can impart a measurable concentration to the total constituent concentration. Aluminum, iron and phosphorus maximum contributions from TSS are close to their effluent limit values. This exercise informs the need for TSS control in order to meet effluent criteria for these constituents. TSS control will occur at the discharge point during operation via the AsWTP.

**VERSION 3**

## EXECUTIVE SUMMARY

The purpose of this Action and Response Plan is to identify areas of concern around the Whale Tail Pit Expansion Project and the associated Hauling road needing to be managed in an organized and timely manner during the annual freshet period to prevent adverse environmental and operational impacts. The Incident Response section of the Plan outlines any future incidents that have the potential to affect off site water or land will be added and would include any specific mitigation and monitoring actions.

The freshet period typically occurs during the annual snow and ice melt sometime around mid-May and extends until the end of July. During this period excess water is created and must be managed through additional pumping and management practices at vulnerable areas around the site. Mitigation techniques, timeframes and specified roles and responsibilities are outlined in this document for each area of concern.

The main areas of concern are the mining pit, the WT WRSF surrounding and pond, the IVR WRSF, the Whale Tail Attenuation Pond, the IVR attenuation Pond, the Whale Tail South Channel, and the IVR Diversion Ditch.

It is important that all water management and associated infrastructure be in good working order and adequate to manage the expected water flows associated with the freshet period; this includes but is not limited to pumps, ditch, culvert and sump maintenance, critical piping system installation and inspection, adequate resource allocation for preparative work and establishing a viable monitoring program for the areas of concern and incident response locations. A summary of the 2021 preparation works and roles and responsibilities is presented in the attached Appendix 1 (2021 Freshet Action Plan Procedures). Appendix 1 will be updated yearly to reflect changes in conditions at the Whale Tail site.

## 1 INTRODUCTION

---

The purpose of the Whale Tail (WT) Freshet Action and Incident Response Plan is to ensure that Agnico can address and manage excess water associated with the freshet season at the Whale Tail site, and to ensure Agnico has implemented specific management and mitigation measures in response to environmental incidents with potential for off site impacts to water or land.

The freshet season is loosely defined as being a period from approximately May 15 – July 30; in some cases, this period of time can extend up to early fall when freezing re-occurs (October 15). There are many areas around the site that are vulnerable to this excess water; the goal is to identify these areas and develop a clear plan with defined roles and responsibilities (among Agnico departments), and to manage the freshet flows.

In addition, several guiding principles are applicable to the formation of this plan. The highest priority principles are:

- 1) to ensure that the health and safety of Agnico employees is protected, especially with respect to mining operations when excess water is present;
- 2) to ensure that mine contact water from runoff or seepage is managed to prevent adverse environmental impacts; and
- 3) to make sure the site is in compliance with the Nunavut Water Board (NWB) License, Part D, Item 21 and Part E, Item 11.

The plan will identify the areas of concern and discuss the potential risks as well as mitigation measures necessary to address the identified issues. The overall site footprint has increased, and experience needs to be gained in identifying key location; lessons learned from the Meadowbank site will provide the necessary guidance. Appendix 1 contains the defined 2021 procedures, the roles and responsibilities and associated timelines. Agnico's intent is to update the Procedural Appendix on a yearly basis. There may be additional mitigation measures for a defined problem area or in some cases a previously defined issue may be permanently rectified.

The main areas of concern are:

- Mining pits and pit walls;
- WRSF pond;
- IVR WRSF;
- Whale Tail South channel;
- IVR Diversion Ditch;
- Whale Tail Attenuation pond;
- IVR Attenuation Pond;
- WT Tank farm;
- Haul road culverts and bridges;
- Pads and roads built since 2020;

- Underground WRSF.

Each area identified above will be discussed in detail below. All areas of concern are considered priorities based on the guiding principles.

## 2 AREAS OF CONCERN

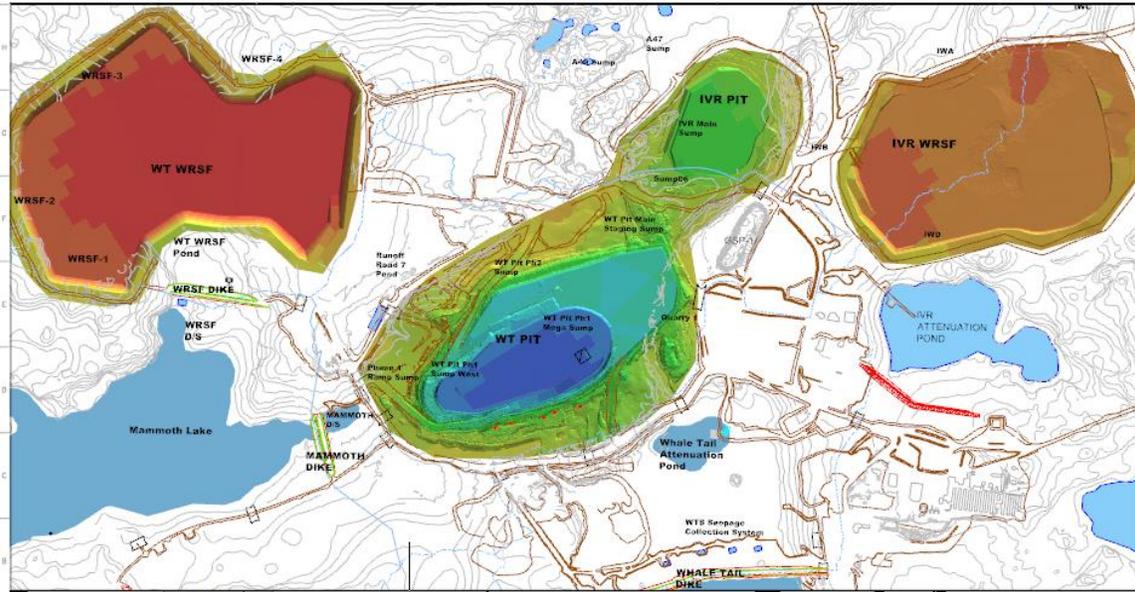

Figure 2-1: View of Whale Tail area

### 2.1 MINING PITS AND PIT WALLS

All permanent ramps, jump ramps, ditches and sumps must be cleaned of all ice and snow before May in order to contain any water resulting from the snow melt. All pumps must be checked and serviced before the month of May. In addition, a check must be completed confirming that all piping systems starting from the different pits leading to the Whale Tail attenuation pond are free of ice by validating pumping values (if pumping systems are active) and/or performing an air test in the pipe with a compressor.

The water management strategy for the pits will be to send water from the WT Pit and IVR Pit area to the IVR Attenuation Pond. Water can also be sent to Whale Tail Attenuation Pond as a secondary water management option.

- A sump and ditch system is used to manage runoff water within the pit footprints. The infrastructures location will be modified or added as required based on the mining sequence.
- Sumps outside of the pit footprint are planned to prevent runoff from reporting to the Pit and to prevent water from ponding against the pit crest;
  - At WT Pit this includes the sumps located at the downstream area of Mammoth Dike and at Road 7;
  - At IVR Pit this include the sump located in former Lake A49 and A47.

## **2.2 WHALE TAIL WASTE ROCK STORAGE FACILITY**

Runoff from the Whale Tail Waste Rock Storage Facility (WT WRSF) is collected by 4 sumps (WT WRSF 1,2,3 & 4) as well as the WRSF pond delimited by WRSF Dike. Water from these sumps is pumped to the WRSF Pond and the WRSF Pond water is pumped to either the IVR Attenuation Pond or the WT Attenuation Pond.

The WT WRSF will require weekly inspections around the perimeter beginning as soon as the freshet starts (May) until freeze up to identify any seepage. In the event that seepage is observed from the WT WRSF, it must be reported to the Environment Departments and samples must be taken to determine the water quality and source. A mitigation plan will be prepared and implemented if necessary. Based on field observation, it may be deemed necessary to remove snow accumulation in the sumps around the WT WRSF to mitigate risk of snowmelt reporting to the surrounding environment. Runoff originating from the WT WRSF ultimately ends up in the WT WRSF pond. In August 2019, seepage from this pond was found to have reported through the WRSF Dike to the Mammoth lake. Remediation measures put in place in 2020 demonstrated to be successful, and will be maintained in 2021. See section 3.1 for further details. Daily inspections of the WRSF Downstream Pond will be required to confirm no seepage is occurring. A pump must be available in this location to pump any water potentially seeping through the structure back into the WRSF Pond.

## **2.3 IVR WASTE ROCK STORAGE FACILITY**

Runoff from the IVR Waste Rock Storage Facility (WRSF) is collected by 4 sumps (IW A,B,C,D). Water from these sumps is sent to the IVR Pond either by pumping or by gravity

The IVR Rock Storage Facility (IVR WRSF) will require weekly inspections around the perimeter beginning as soon as the freshet starts (May) until freeze up to identify any seepage and ensure that the gravity flow to the IVR Attenuation Pond are occurring as planned. In the event that seepage is observed from the IVR WRSF, it must be reported to the Environment Departments and samples must be taken to determine the water quality and source. A mitigation plan will be prepared and implemented if necessary. Based on field observation, it may be deemed necessary to remove snow accumulation in key locations around the IVR WRSF to mitigate risk of snowmelt reporting to the surrounding environment.

## **2.4 WHALE TAIL SOUTH DIVERSION CHANNEL**

The South Whale Tail Diversion Channel was constructed in 2020. This channel allows water from the Whale Tail South watershed (2,400 ha) to report to Mammoth Lake, and subsequent downstream lakes. In 2020, the first year of operation of the channel, no TSS exceedances occurred, and the channel performed as designed. In early May, partial snow removal will be required in this infrastructure to form a preferential water path and prevent snow blockage. Daily inspection at the start of freshet will be required until freshet is completed and following rain events, to ensure no contaminant is transported into Mammoth Lake. Turbidity barriers were designed by SNC-Lavalin and installed by Agnico Eagle in 2020. They were left in place at the end of 2020 to

secure subsequent freshets. **Error! Reference source not found.** demonstrate the location and design of turbidity barrier. Barrier inspection will be required to ensure they perform as intended.

Figure 2-2: Turbidity Barrier Location

## 2.5 IVR DIVERSION DITCH

The IVR Diversion Ditch was constructed during the fall of 2020, and will be commissioned for freshet 2021. The IVR Diversion Ditch serves to divert the watershed reporting to the IVR Pit towards the C-Watershed. This will reduce the amount of contact water to manage on site. Significant attention and monitoring will be required for the commissioning of this infrastructure. In early May, partial snow removal will be required in this infrastructure to form a preferential water path and prevent snow blockage. Daily inspection at the start of freshet will be required until freshet is completed and following rain events, to ensure no contaminant is transported into the surrounding environment. Additional mitigation measures may be required, such as the use of straw logs, based on field observations.

## 2.6 WHALE TAIL ATTENUATION POND

The Whale Tail Attenuation Pond is the secondary contact water management basin on site. Contact water from surrounding infrastructure is pumped to the pond. From there, Whale Tail Attenuation Pond water can be pumped to either the IVR Attenuation Pond or the AsWTP, for

treatment, if required, and discharge to approved final effluent locations within Whale Tail South or Mammoth lake. The plant's treatment abilities were designed to remove TSS and arsenic. All piping and the discharge diffuser must be inspected prior to freshet, in order to have all installations in place to proceed with pumping and/or treatment activities during freshet. The pond water levels will be managed closely and inspected regularly.

## **2.7 WHALE TAIL DIKE SEEPAGE**

Water from the Whale Tail Dike seepage is reporting to the WT Attenuation Pond through either a pumping system or by gravity. If water quality criteria are met, it is possible for the system to discharge directly to WTS. In 2021, the system is not expected to be put in operation due to the current water quality.

## **2.8 IVR ATTENUATION POND**

The IVR Attenuation Pond is the main contact water management basin on site. Contact water from surrounding infrastructure is pumped to the pond. From there, water can be discharged to approved final effluent locations within Whale Tail South or Mammoth lake, or may be sent to the AsWTP, for treatment, if required, prior to discharge. The plant's treatment abilities were designed to remove TSS and arsenic. All piping and the discharge diffuser must be inspected prior to freshet, in order to have all installations in place to proceed with pumping and/or treatment activities during freshet. The pond water levels will be managed closely and inspected regularly.

## **2.9 WHALE TAIL FUEL TANK FARMS**

The main fuel farm containments were built in 2019, and will be monitored throughout freshet. Snow and ice accumulation within the fuel tank farms must be adequately managed to prevent overflow to the environment and/or damage to the fuel handling systems. The Energy and Infrastructure Department will advise the Environmental Department of their intent to pump the containment area once ice/snow begins to melt. Water samples will be taken in accordance with the Water License to ensure compliance prior to its release. A notice must be provided to the Inspector 10 days prior to this pumping activity. Once sample results have been obtained, the Environmental Department will advise the Energy and Infrastructure Department. If sample results permit, the pumping may begin; to direct water to the tundra/ground in a way to prevent erosion. In the event that the water sample results do not meet discharge criteria the water could be trucked in a tanker and transported to the Meadowbank site to be disposed of in the TSF or placed in containers for shipment south as hazmat.

## **2.10 HAUL ROAD CULVERTS AND BRIDGES**

Daily inspections will be undertaken starting in May at all culverts along the Haul road to ensure that water during freshet is flowing freely and no erosion is occurring. If elevated TSS/Turbidity levels are observed sampling will occur and the results assessed. Turbidity barrier will be installed if required. The Mine department will also be advised if severe erosion/scouring is observed. In addition, snow and ice removal may be required to allow the water to flow as per design

specifications. Daily inspections will be performed during the freshet period by the Environment department.

### **2.11 2020-2021 PAD AND ROAD CONSTRUCTION**

In 2020, the expansion project was approved, meaning many pads and roads were built around site that will experience their first snowmelt. Weekly inspections at the start of snowmelt will be required to monitor for potential erosion and sediment transport. Mitigation measures may be required to minimize transport of sediments towards water bodies. See below for a list of such constructions:

- IVR Pit Ring Road;
- IVR WRSF ring road;
- Whale Tail main pad extension;
- IVR Dike;
- New road culverts – Road 23 and culverts drain towards IVR attenuation pond;
- Various pad extensions.

### **2.12 UNDERGROUND WRSF WATER COLLECTION SYSTEM**

The Underground WRSF Water Collection System was built in 2019 to collect any water running off the underground infrastructure, and direct runoff water into GSP1. Steaming of culverts may be necessary if snow or ice blockage are identified prior to the start of freshet. Weekly inspection will be required during freshet to validate operationality and liner integrity of collection system.

### 3 INCIDENT RESPONSE

---

#### 3.1 WRSF POND SEEPAGE

In August 2019, water originating from the WRSF Pond seeped through the dike and reported to the Mammoth Lake. Immediate actions taken were to build an access road to the downstream portion of the dike, in order to excavate a small sump and pump the seepage water into WRSF pond. Furthermore, WRSF Pond was emptied and maintained dry. Downstream pumping stopped on September 30th, when the reporting flow and surrounding had frozen. In October 2019, the KIA conducted a sample analysis of the lake bed sediments in Mammoth Lake. The report concluded the seepage did not have a measurable impact on metal quantities of the Mammoth Lake sediments. In 2020, follow-up lake bed sediments samples were analyzed and support the 2019 conclusions.

The following mitigation measure are implemented:

- Operational water level was reviewed to keep water as low as possible in the WRSF pond, as recommended by the MDRB;
- Aggradation of permafrost into the dike's foundation by:
  - Construction of a thermal berm in 2020 on the upstream portion of the dike;
- Access road to the downstream area was constructed to facilitate inspection;
- Various environmental monitoring program:
  - Monthly limnology profile of Mammoth Lake during winter and open water conditions;
  - Mammoth Lake included in a Core receiving environmental monitoring program; and
  - A sediment sampling campaign executed in Mammoth Lake.

#### 3.2 ADAPTIVE WATER MANAGEMENT STRATEGY

An Adaptive Water Management Plan will be developed to document specific mitigation measures and associated management actions to be taken when specified thresholds are exceeded. Mitigation measures may include special studies, operational changes, revised or new water and waste management systems, structures and/or facilities, or implementing mitigation activities to prevent, stabilize or reverse a change in environmental conditions or to otherwise protect the receiving environment. The Adaptive Management Plan would be reviewed periodically to account for the dynamics of mine construction and operation, and to adjust the adaptive management strategy as needed.

Various level thresholds were identified for surface water management, based on the capacity of different water management infrastructure to retain water on site. The objective is to trigger management strategy actions based on the capacity of these structures. The main management response is based on increasing the discharge rate especially when water is meeting effluent discharge criteria.

#### **4 SNOW MANAGEMENT**

---

A snow management procedure has been developed internally in 2020 and will be updated annually. Refer to Appendix 2 for the snow management map. Temporary snow storage dumps and snow accumulation areas of concern were identified on a map. Removal will be managed accordingly.

**APPENDIX 1**

**2021 Freshet Action Plan Procedure**

Section	Area of Concern	Role/Action	Responsibilities	Dates
<b>2.1 MINING PITS AND PIT WALLS</b>				
2.1	Mining Pit and Pit walls - General	1) Clean all ice, mud and snow on all permanent ramps, jump ramps, etc.	Mine Operations	Before May
		2) Check and service all pumps.	E&I (Energy and Infrastructure) and Maintenance	Before May
		3) Check that all piping systems starting from the pit leading to the Attenuation ponds are free of ice by validating pumping values (if pumping systems active) and/or performing an air test in the pipe with a compressor.	E&I/Mine Operations	Before May
<b>2.2 WHALE TAIL WASTE ROCK STORAGE FACILITY</b>				
2.2.	WT WRSF Inspection	1) Weekly inspection around the RSF perimeter to identify any seepage.	Env. Department	May - as soon as freshet starts until freeze up
		2) Pump if required from the WRSF periphery to WRSF Pond	E&I	May - as soon as freshet starts until freeze up

		3) If seepage observed notify Env Department AND sample for Water License Parameters.	Env. Department	May - as soon as freshet starts until freeze up
<b>2.3 IVR WASTE ROCK STORAGE FACILITY</b>				
2.3.	IVR WRSF Inspection	1) Weekly inspection around the IVR WRSF perimeter to identify any seepage.	Env. Department	May - as soon as freshet starts until freeze up
		2) Pump if required from the IVR WRSF periphery to IVR attenuation pond	E&I	May - as soon as freshet starts until freeze up
		3) If seepage observed notify Env Department AND sample for Water License Parameters.	Env. Department	May - as soon as freshet starts until freeze up
<b>2.4 WHALE TAIL SOUTH DIVERSION CHANNEL</b>				
2.4	Whale Tail South Diversion Channel	1) Daily inspection - keep record	Env. Department	May - until freshet complete and after rain events
		2) Install mitigation measures, if needed (elevated TSS observed), and maintain	Env. Department	May - until freshet complete and after rain events

2021 FRESHET ACTION AND INCIDENT RESPONSE PLAN

		3) Sample monitoring for TSS, if excess turbidity observed - use external lab.	Env. Department	May - until freshet complete and after rain events
		4) Report any discharge of TSS to Mammoth Lake to ECCC/NWB (if grab > 30 mg/L).	Env. Department	May - until freshet complete and after rain events
<b>2.5 IVR DIVERSION DITCH</b>				
2.5	IVR Diversion Ditch	1) Daily inspection - keep record	Env. Department	May - until freshet complete and after rain events
		2) Install mitigation measures, if needed (elevated TSS observed), and maintain	Env. Department	May - until freshet complete and after rain events
		3) Sample monitoring for TSS, if excess turbidity observed - use external lab.	Env. Department	May - until freshet complete and after rain events
		4) Report any discharge of TSS to Mammoth Lake to ECCC/NWB (if grab > 30 mg/L).	Env. Department	May - until freshet complete and after rain events
<b>2.6 WHALE TAIL ATTENUATION POND</b>				

2.6	Whale Tail Attenuation Pond	1) Set-up pumping of the WT Attenuation Pond to prevent water from flowing into the pit area, keeping track of all daily volumes	E&I	At all time
		2) Notify Environmental Department before any environmental discharge.	E&I	At all time
		3) Inspect all piping and discharge diffuser	E&I	May
<b>2.7 IVR ATTENUATION POND</b>				
2.7	IVR Attenuation Pond	1) Set-up pumping of IVR Attenuation Pond through the AsWTP, keeping track of all daily volumes	E&I	At all time
		2) Notify Environmental Department before any environmental discharge.	E&I	At all time
		3) Inspect all piping and discharge diffuser	E&I	May
<b>2.8 FUEL TANK FARMS</b>				
2.8	WT Tank Farm	1) E&I Dept to advise Env Dept in advance of intent to pump once ice melts in containment area.	E&I and Env. Department	Probably mid-June and September
		2) Sample water in accordance with Water License to ensure compliance with limits prior to release.	Env. Department	Probably mid-June and September

2021 FRESHET ACTION AND INCIDENT RESPONSE PLAN

		3) Provide notice to Inspector 10 days prior to pumping.	Env. Department	Probably mid-June and September
		4) Advise Energy and Infrastructure Dept if pumping can begin based on sample results.	Env. Department	Probably mid-June and September
		5) Pump to tundra/ground or Meadowbank TSF. <b>NOTE: The water cannot be pumped out to the tundra if it does not meet the Water License criteria.</b>	E&I	Probably mid-June and September
<b>2.10 RECENT PAD AND ROAD CONSTRUCTIONS</b>				
2.10	Recent pad and road constructions	1) Daily inspection of culverts around site (Road to emulsion plant, IVR access road)	Env. Department	May and after rain events
		2) Weekly inspection of toes of constructions built in the last year.	Env. Department	May and after rain events
		3) Sample for TSS and Turbidity if elevated TSS observed.	Env. Department	May - until freeze up
		4) Notify E&I Dept if severe erosion/scouring observed - for repair action.	Env. Department	May - until freeze up
		5) Install mitigation measures if required.	Env. Department	May - until freeze up

3.0 INCIDENT RESPONSE				
3.1	WRSF Pond Seepage	1) Daily inspection - keep record	Env. Department	May - until freshet complete and after rain events
		2) Maintain WRSF Pond as dry as possible	E&I	May - until freeze up
		3) Pump any water reporting to the WRSF downstream water collection system – Volumes required to be documented	E&I/Engineering	May - until freeze up
		4) Sample upstream and downstream	Env. Department	May - until freeze up
		5) Report any discharge of TSS to Mammoth Lake to ECCCNWB (if grab > 30 mg/L).	Env. Department	May - until freshet complete and after rain events
