EXECUTIVE SUMMARY

The Hope Bay Mine, owned by Agnico Eagle Mines Limited, is located within the Hope Bay greenstone belt, on the south shore of Melville Sound of the West Kitikmeot region of mainland Nunavut. It is situated on an 80 by 20 km property that consists of three main gold deposits: Doris, Madrid, and Boston. The Doris gold deposit is currently the only deposit that is actively mined.

Roberts Bay is the receiving environment for effluent discharge associated with the Doris Mine, covering an area of approximately 1,430 hectares (ha) on the south shore of Melville Sound, to the east of Hope Bay. Discharge from the Hope Bay Mine includes groundwater and freshwater sources, including from the underground workings, the tailings impoundment area, or a combination of both. Effluent is discharged into Roberts Bay via an insulated pipeline to a multi-port diffuser. The Hope Bay Mine began discharging effluent into Roberts Bay at a rate in excess of 50 cubic metres (m^3) per day, becoming subject to the Metal and Diamond Mining Effluent Regulations (MDMER) under the federal Fisheries Act on February 1st, 2020. The objective of EEM (Environmental Effects Monitoring) is to determine whether mine effluent is causing an effect on the fish population, the use of fisheries resources (e.g., mercury accumulation in fish tissues), and/or fish habitat (benthic invertebrate communities).

Effluent quality met all MDMER monthly mean and grab sample concentration limits and showed no acute toxicity to test organisms. Annual mean and grab sample mercury and selenium concentrations throughout the Phase 1 EEM were below the triggers for fish tissue sampling under EEM. Sublethal toxicity results showed that effects were observed to Giant Kelp in 2020 and 2021 but not in 2022. Rapid dilution of effluent within Roberts Bay and the concentrations at which effects were observed poses low risk to aquatic life within the receiving environment.

The influence of the Hope Bay Mine discharge on Roberts Bay is nearly undetectable. Mean concentrations of ammonia, nitrate, and manganese were slightly elevated at the effluent-exposed area compared to the reference area for mid-depth samples in 2021, indicating the presence of effluent, however no observable difference was present for other years, or for any other parameters over the duration of Phase 1. Phosphorus mean annual concentrations exceeded chronic CWQG (Canadian Water Quality Guidelines) during one sample year, however concentrations were elevated at both the effluent-exposed and reference areas, indicating a natural influence within Roberts Bay, rather than a mine-related influence.

Within Roberts Bay, effluent mixing occurs rapidly, resulting in a limited effluent plume and negligible concentrations of mine-indicator parameters in receiving environment samples. Based on this, no sublethal toxicity to test organisms in 2022, and no impairment to water quality

within the receiving environment, the Hope Bay Mine discharge is likely not having an impact on Roberts Bay.

1 INTRODUCTION

1.1 Background

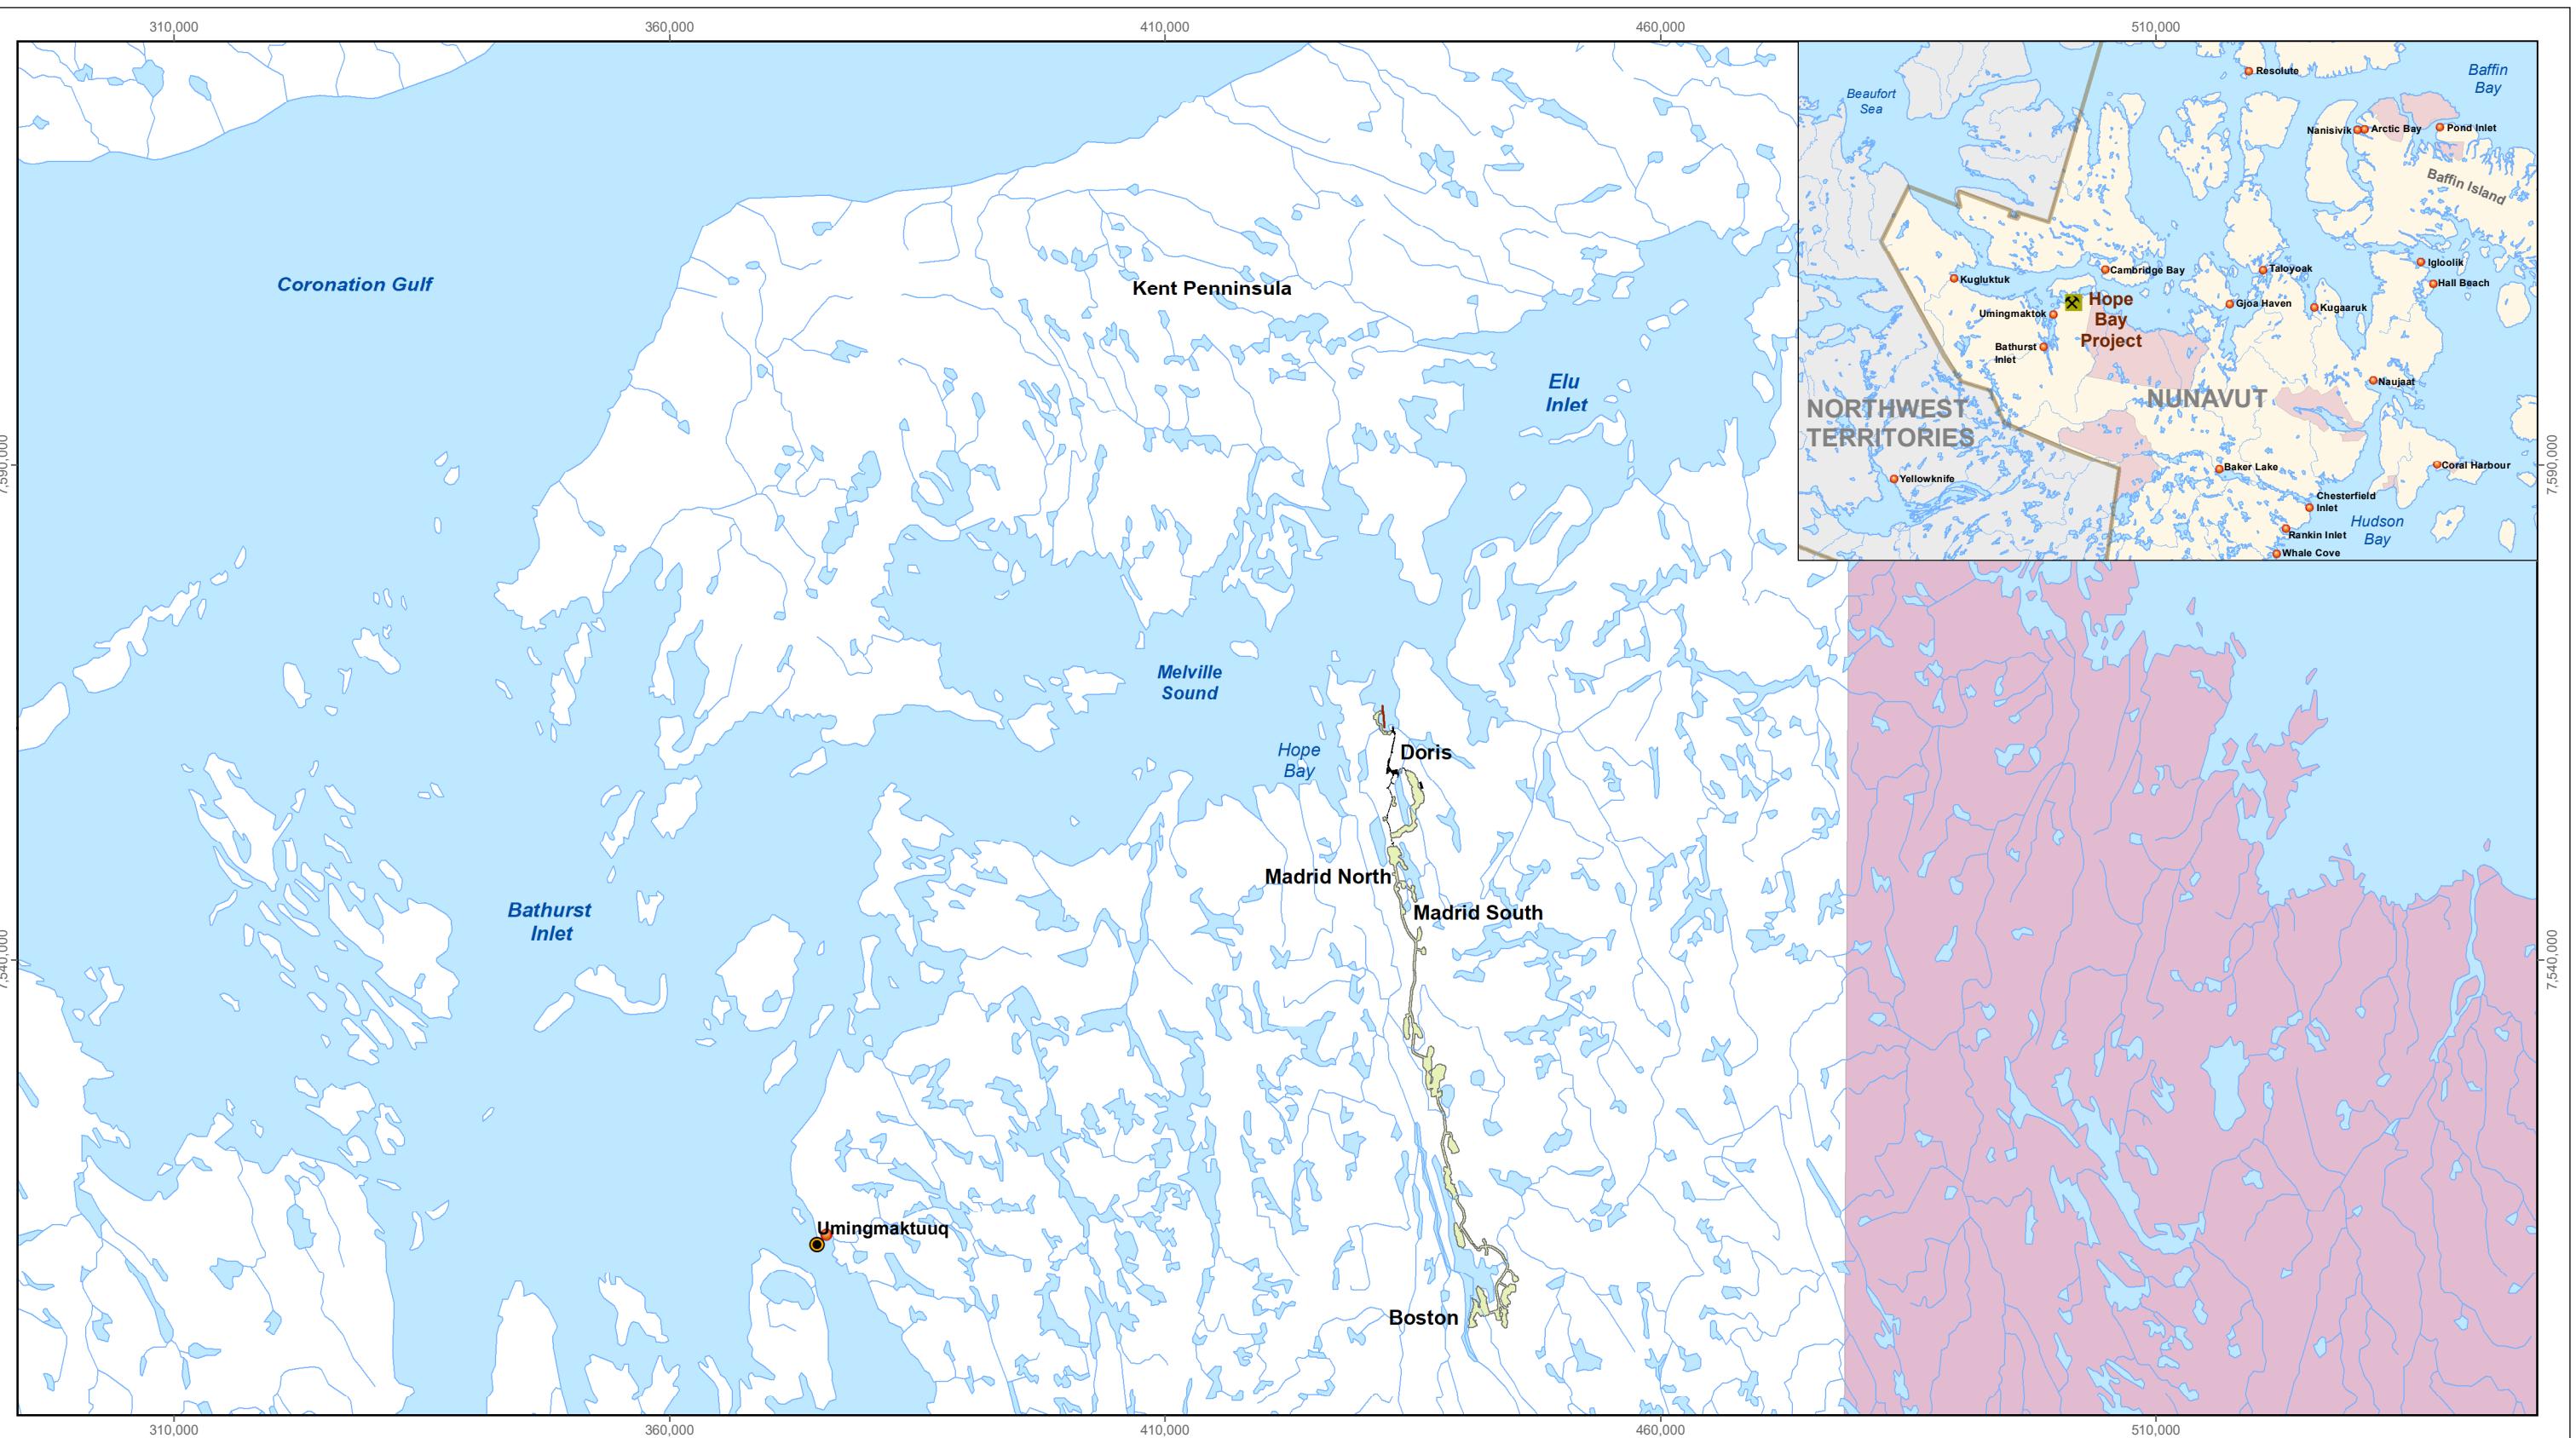

Agnico Eagle Mines Ltd. (AEM) Hope Bay Mine is located within the Hope Bay greenstone belt, along the south shore of Melville Sound in the West Kitikmeot region of mainland Nunavut (Figure 1.1). The Hope Bay Project is situated on an 80 by 20 km property that encompasses three main gold deposits: Doris, Madrid, and Boston. The Doris gold deposit is the northernmost deposit and is currently mined by AEM. The Madrid deposit is also located in the northern region of the property, just south of the Doris Mine. The Boston deposit is at the south end of the property near Aimaokatalok Lake (Figure 1.1). Nearby communities include Cambridge Bay (Iqaluktuttiaq), Bay Chimo (Umingmaktok), and Bathurst Inlet (Kingaok).

Exploration and mine development activities within the Hope Bay greenstone belt began in the late 1980s. Development of mining infrastructure continued until 2011 when the Hope Bay Project was placed into care and maintenance. In 2013, TMAC finalized the purchase of the Hope Bay Project from Newmont Corporation, which included all exploration and mineral rights associated with the Hope Bay Project, as well as the Doris Gold Mine and its existing permits, authorizations, and licenses. In March 2013, TMAC resumed exploration and baseline environmental monitoring activities at the Doris Gold Mine. Mine development resumed in the summer of 2015 and commercial gold production officially began in 2017. In 2021, Agnico Eagle Mines Ltd. finalized the purchase of the Hope Bay Mine from TMAC Resources. Doris Gold Mine operations ceased production in February 2022, while advanced exploration activities at the site continue.

1.2 Discharge Infrastructure Overview

Roberts Bay is the receiving environment for effluent discharge associated with the Doris Mine and is also the location of a marine cargo dock constructed to facilitate shipments to and from site. Roberts Bay covers approximately 1,430 hectares (ha) on the south shore of Melville Sound, to the east of Hope Bay (Figure 1.2). Freshwater enters Roberts Bay from a number of tributaries, with the two largest being Little Roberts Lake Outflow and Glenn Lake Outflow. Water within Roberts Bay exchanges freely with the water in Melville Sound. Ice cover is present on Roberts Bay from late September through late June, with open water present through the remaining months (ERM 2016a). During ice covered months, 1 to 2 m of ice forms on Roberts Bay, sheltering it from atmospheric winds and reducing circulation. Through warming, wind, and freshwater inputs during the open water season, circulation within the bay increases, resulting in a ten-fold increase in the exchange rate with Melville Sound (ERM 2016a). Tidal ebb and flow currents are weak within the bay. The south shore of Roberts Bay is adjacent to infrastructure and activities associated with the Hope Bay Project.

Figure 1.2

The Hope Bay Project began depositing effluent into Roberts Bay at a rate in excess of 50 cubic metres (m^3) per day on February 1, 2020 (Appendix A). Notification of the Final Discharge Point was provided to Environment and Climate Change Canada (ECCC) on March 16, 2020, as required under Section 9 of the Metal and Diamond Mining Effluent Regulations (MDMER; Government of Canada 2022).

Discharge from the Hope Bay Project includes saline groundwater from the underground workings (up to 25 ppt salinity) and freshwater from the Tailings Impoundment Area (TIA, 0.2 ppt salinity; ERM 2016b). During discharge, effluent released would be either from a combination of the two sources or from one of the sources depending on water management needs at the site. Under the original discharge conditions, effluent was initially pumped from the outfall berm through a single 2.4 km insulated pipeline to a multi-port diffuser located at a depth of 40 m and 575 m from the nearest shoreline. The diffuser is approximately 35 m long and includes four pairs of 4" ports (eight total) situated 8.2 m apart and 1.2 m above the sea floor, discharging horizontally. Effluent salinity would fluctuate based on the source of water but would be expected to be more buoyant than the receiving environment and would therefore rise in the water column before becoming fully mixed at a trapping depth¹. Initial modelling results indicated effluent would be quickly diluted, with concentrations 15 m from the diffuser reaching effluent dilution ratios of 160:1 (0.6%) at trapping depth when the most saline and coldest groundwater is discharged under ice² (ERM 2016b). Under the original discharge conditions, the predicted trapping depth would fluctuate, ranging from 28 to 35 m depth under ice, and 34 to 36 m during the open water season, based on effluent source and season.

During maintenance of the Roberts Bay Discharge System (RBDS) in fall 2020, portions of the submerged discharge line in Roberts Bay became buoyant and rose to the underside of the sea ice. To resolve the issue, the discharge line was cut at 1.4 km from shore to release the trapped air and enable both sections of the line to be laid back down to the ocean bottom. This resulted in the need to modify the discharge location of the RBDS, which now ended at 20 m depth, 1.4 km from shore, rather than 40 m depth, 2.4 km from shore. Information in the form of a self-assessment was provided to the NIRB on February 19, 2021 (Agnico Eagle, 2021), including the plan for the installation of a diffuser at the new location, updated modelling (with and without a diffuser) and an assessment of monitoring that had been conducted (Minnow 2020; 2021a,b). The NIRB subsequently confirmed that the new discharge location did not constitute a significant project modification.

¹ The depth at which effluent will no longer rise in the water column after mixing.

² This represents worst-case conditions based on modelled effluent mixing scenarios.

In order to maintain water balance within the TIA and water from the underground mine, Hope Bay Mine discharged effluent through the 2021 season from the modified discharge location, with planned installation of a diffuser during the open water season, as outlined during previous communications with the NIRB (Appendix A). In July 2021, the cut section of the pipe was successfully removed from the seabed as planned. However, due to troubleshooting of some air entrainment in the pipeline, the reattachment of the diffuser was postponed to September. The diffuser reattachment team was mobilized to site in mid-September, however, during this time the boats planned to be used for this work had engine failures and/or were taking in water, rendering the work unsafe to be completed. Repairs to the boats could not be completed before the freezing of Roberts Bay. Consequently, the diffuser could not be installed as planned. Reinstallation of the diffuser was completed in August 2022, with discharge of effluent through the diffuser commencing on August 22nd, 2022.

1.3 Pertinent Regulations

Discharge of effluent at a rate greater than 50 m³ per day on February 1, 2020, triggered the Metal and Diamond Mining Effluent Regulations (Government of Canada, 2022; MDMER; SOR/2002-222) under the federal *Fisheries Act*. As part of the MDMER, Environmental Effects Monitoring (EEM) is required. This includes conducting effluent characterization, sublethal toxicity testing, receiving environment water quality monitoring, and biological monitoring (if required) of fish health, benthic invertebrate community health, and/or fish tissue concentrations of mercury and selenium. An overview of MDMER monitoring requirements is presented in Table 1.1.

In accordance with the MDMER, a study design for the first EEM phase (herein referred to as the Phase 1 EEM) was submitted to ECCC in January 2021, within one year of Hope Bay Mine becoming subject to the regulations (Minnow 2021c). Upon review of the study design, seven action items were identified by a technical advisory panel (TAP) consisting of representatives from ECCC, Crown-Indigenous Relations and Northern Affairs Canada (CIRNAC), and the Nunavut Water Board (NWB) in a letter dated March 31st, 2022 (Appendix A). An addendum to the Study Design was prepared that included a detailed response to address each of these action items, which was submitted to ECCC on May 17th, 2022 (Minnow 2022; Appendix A). Subsequent approval of the Study Design (and associated addendum) was received from ECCC on May 31st, 2022 (Appendix A).

Based on the requirements stipulated within the MDMER, the Hope Bay Mine Phase 1 EEM Interpretive Report includes an assessment of effluent quality, acute and sublethal toxicity test results, and receiving environment monitoring. No biological monitoring was required for the Phase 1 EEM as effluent concentrations 100 and 250 m from the discharge were below 1%

(benthic invertebrate and fish health triggers, respectively) and mercury and selenium concentrations were below trigger concentrations in effluent (Table 1.1).

Table 1.1: MDMER Monitoring Requirements, Hope Bay Mine

Component	Timeframe	MDMER Requirement	Trigger	Frequency ^c
Effluent Monitoring and Characterization	Continuous	Reporting discharge volumes, chemistry, acute toxicity, sublethal toxicity	Triggered when Hope Bay Mine commenced effluent discharge into Roberts Bay	Discharge volume monitoring, weekly sampling for deleterious substances, temperature, salinity, and pH as per MDMER ^a , monthly acute toxicity, and quarterly effluent chemistry sampling ^b
Sublethal Toxicity Testing	Continuous	Sublethal toxicity testing of effluent using fish species, invertebrate species, and algal species	Triggered when Hope Bay Mine commenced effluent discharge into Roberts Bay	Twice per year for the first EEM phase, 4 times per year after the first 3 years on the most sensitive species
Receiving Environmental Water Quality	Continuous	Routine monitoring at reference and exposed areas	Triggered when Hope Bay Mine commenced effluent discharge into Roberts Bay	Three times per year, in-situ water quality, salinity, water chemistry ^d , percent effluent concentration calculations using effluent indicator parameters
Benthic Invertebrate Community Health	3 year cycle	To be completed if effluent concentrations are >1% 100 m from the discharge during the 3-year period between study design submissions, unless no effects have been observed over the previous two studies	Not triggered , effluent concentrations were less than 1% at 100 m from the discharge in the receiving environment	If triggered, benthic invertebrate sampling at both the effluent-exposed and reference sites in Roberts Bay, including statistical comparisons, to be completed once per cycle
Sediment Quality	3 year cycle	Required if sampling benthic invertebrates	Not triggered , effluent concentrations were less than 1% at 100 m from the discharge in the receiving environment	If triggered, sediment chemistry, particle size, and statistical comparisons across effluent-exposed and reference sites, to be completed once per cycle
Fish Health	3 year cycle	To be completed if effluent concentrations are >1% 250 m from the discharge during the 3-year period between study design submissions, unless no effects have been observed over the two previous studies	Not triggered , effluent concentrations were less than 1% at 250 m from the discharge in the receiving environment	If triggered, fish health and fish populations studies, statistical comparisons of endpoints across effluent-exposed and reference stations, to be completed once per cycle
Fish Tissue Chemistry Selenium	3 year cycle	To be completed if concentrations of total selenium in effluent are equal to or greater than 10 µg/L at any time during the previous three years, or if effluent characterization reveals an annual mean concentration of total selenium which is equal to or greater than 5 µg/L, based on a calendar year	Not triggered , due to low levels of selenium concentrations in effluent during monthly sampling, and as an annual mean concentration	If triggered, fish tissue sampling to be completed, assessing selenium concentrations in muscle and/or ovary tissues
Fish Tissue Chemistry Mercury	3 year cycle	To be completed if effluent characterization reveals an annual mean concentration that is equal to greater than 0.10 µg/L, based on a calendar year, or unless the results of the previous two monitoring studies indicate no effect on fish tissue from mercury	Not triggered , due to low levels of mercury concentrations in effluent during monthly sampling, and as an annual mean concentration	If triggered, fish tissue sampling to be completed, assessing mercury concentrations in muscle tissue

Notes: MDMER - Metal and Diamond Mining Effluent Regulations

^a Deleterious substances include arsenic, copper, cyanide, lead, nickel, zinc, total suspended solids, radium-226, and un-ionized ammonia.

^b Effluent characterization includes hardness, alkalinity, electrical conductivity, temperature, and concentrations of aluminum, cadmium, iron, mercury, molybdenum, selenium, nitrate, chloride, chromium, cobalt, sulphate, thallium, uranium, phosphorus, manganese

^c Frequency of sampling in the receiving environment was dependent on ice-free conditions. Sampling usually occurred a maximum three times per year. Effluent was sampled only during times of discharge.

^d Included effluent indicator parameters (ammonia, copper, and manganese), as well as *in-situ* water quality and water chemistry (metals, nutrients, and anions).

^e If laboratory reporting limits (LRL) are equal to or above these concentration values four or more times in a calendar year, a fish tissue chemistry study must also be conducted.

2 METHODS

2.1 Overview

The Hope Bay Mine Phase 1 EEM Interpretive Report presents the results of effluent quality monitoring, toxicity testing, and receiving environment water quality monitoring completed by the mine from 2020 through 2022. As effluent concentrations in the receiving environment were below the triggers for biological monitoring during the period assessed for the study design (Appendix A, Minnow 2022), these components are not included within the report.

Water quality monitoring in Roberts Bay is conducted directly over the diffuser (effluent-exposed) and at a reference area located on the east side of Roberts Bay (Figure 2.1). A description of the methods used for collection effluent and receiving water samples and data analysis are provided in the sections below.

Effluent monitoring for the Roberts Bay Discharge (RBD1; effluent volume, quality, and acute/sublethal toxicity testing) and receiving environment water quality monitoring was conducted in accordance with MDMER requirements. As part of these requirements, AEM provided an annual effluent and water quality monitoring report to ECCC by March 31st of the following year that included sampling locations, dates, methods, and results together with information on quality assurance and quality control (QA/QC) (Government of Canada 2022).

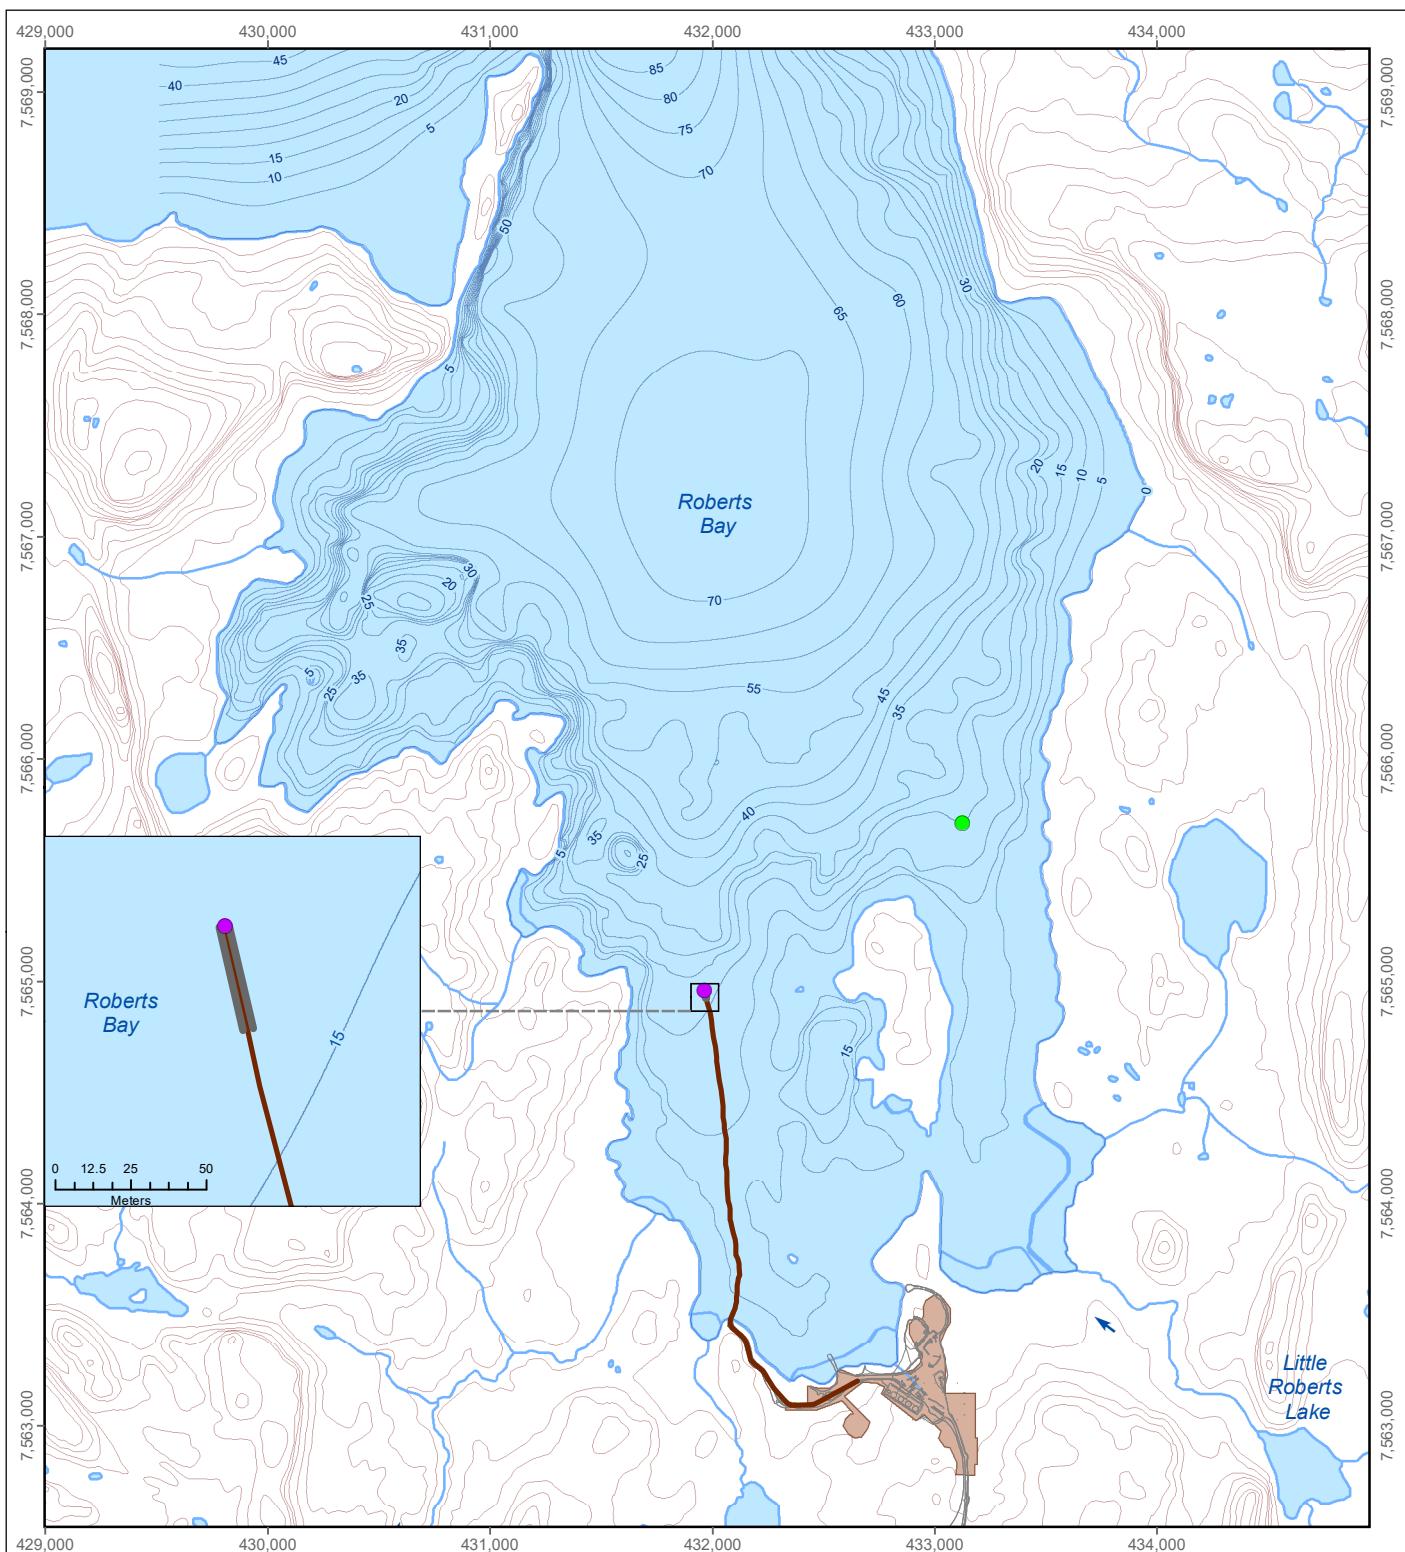

2.2 Effluent Volume and Quality

Effluent quantity and quality monitoring included routine MDMER monitoring (volume, deleterious substances, and acute toxicity), effluent characterization, and effluent sublethal toxicity testing. The volume of treated effluent discharged from the TIA to Roberts Bay is monitored continuously in units of cubic meters (m^3) discharged daily at the final effluent discharge location, referred to as Station RBD1 (i.e., “Roberts Bay Discharge”). Deleterious substances (arsenic, copper, lead, nickel, zinc, total suspended solids, total cyanide, radium-226, and un-ionized ammonia), were monitored at least once per week during periods of effluent discharge.

Effluent characterization, including temperature (field), analysis of electrical conductivity (EC, field), pH (field), hardness, alkalinity, total suspended solids (TSS), total dissolved solids (TDS), salinity, oxidation reduction potential (ORP), anions and nutrients, and total metals/metalloids³, was conducted at least once per week during periods of effluent discharge in

³ The list of total metals/metalloids analyzed for effluent characterization included all metals, nutrients, and anions required under the MDMER (aluminum, cadmium, chromium, cobalt, iron, manganese, mercury, molybdenum, phosphorus, selenium, thallium, and uranium) plus other metal/metalloids, nutrients, and anions .

minnow environmental inc. <small>A Trinity Consultants Company</small>		Figure 2.1

accordance with MDMER requirements.⁴ Effluent samples were collected by Hope Bay Mine personnel as grab samples directly from the discharge pipe and were sent to various labs for analysis (ALS Vancouver, BC and Bureau Veritas Burnaby, BC). Concentrations of deleterious substances were compared to applicable MDMER limits and annual means were calculated to assess changes in effluent quality over time. Mercury and selenium concentrations in mine effluent were compared to the EEM fish tissue survey triggers based on individual values, annual means, and laboratory reporting limits (LRL) as specified under the MDMER (Schedule 5, Part 2, Sections 9(1)[c] and 9(1)[d]) to verify that a fish tissue survey was not required for the Phase 1 interpretive report.

Acute lethality testing was conducted at a minimum frequency of monthly, and sublethal toxicity testing was conducted twice per calendar year, using TIA effluent collected at Station RBD1 during periods of effluent discharge over the Phase 1 EEM period (i.e., 2020 to 2022). Final effluent samples for acute and sublethal toxicity testing were collected into labelled plastic containers (20 litre [L] and 10 L containers, respectively) provided by the toxicity laboratory, and placed into coolers packaged with ice packs. The effluent samples were shipped to various labs, (Nautilus Environmental in Burnaby, BC; Harris Industrial Testing Service Ltd. (HITS) in Waverley, NS; and Bureau Veritas in Burnaby, BC) for testing, ensuring appropriate hold times were met. Acute toxicity tests were conducted using the planktonic invertebrate *Acartia tonsa*, rainbow trout (*Oncorhynchus mykiss*), and/or the threespine stickleback (*Gasterosteus aculeatus*) in accordance with MDMER⁵ requirements and procedures (Environment Canada 2000a,b,; Environment Canada 2019; Government of Canada 2022). Following MDMER requirements, salinity concentrations exceeded 10 parts per thousand several times in 2021 and 2022 (Figure 2.2, which resulted in conducting acute toxicity testing on the threespine stickleback for these months during effluent discharge rather than rainbow trout).

Due to RBD1 effluent discharging into a marine environment, sublethal toxicity testing was conducted using Giant Kelp (*Macrocystis pyrifera*; 48-hour germination and germ tube growth test), an echinoderm (*Strongylocentrotus purpuratus*; 10-minute fertilization/reproduction test), and Pacific Topsmelt (*Atherinops affinis*; 7-day survival and growth test) using standard test methods (i.e., Environment Canada 2001; 2011; USEPA 1994; 1995)

⁴ Effluent characterization monitoring for Hope Bay final effluent (Station RBD1) was conducted at a frequency greater than that required under the MDMER (i.e., more frequently than once per calendar quarter) to better track effluent treatment performance.

⁵ As per MDMER regulations, if the salinity value of effluent is greater than four parts per thousand (ppt) and the effluent is deposited into marine waters, the mine shall conduct acute lethality testing on *Acartia tonsa*, replacing *Daphnia magna* as the test species. (Government of Canada, 2022). Salinity in effluent at Hope Bay Mine exceeded four ppt for most of the duration of the Phase 1 EEM (Figure 2.2).

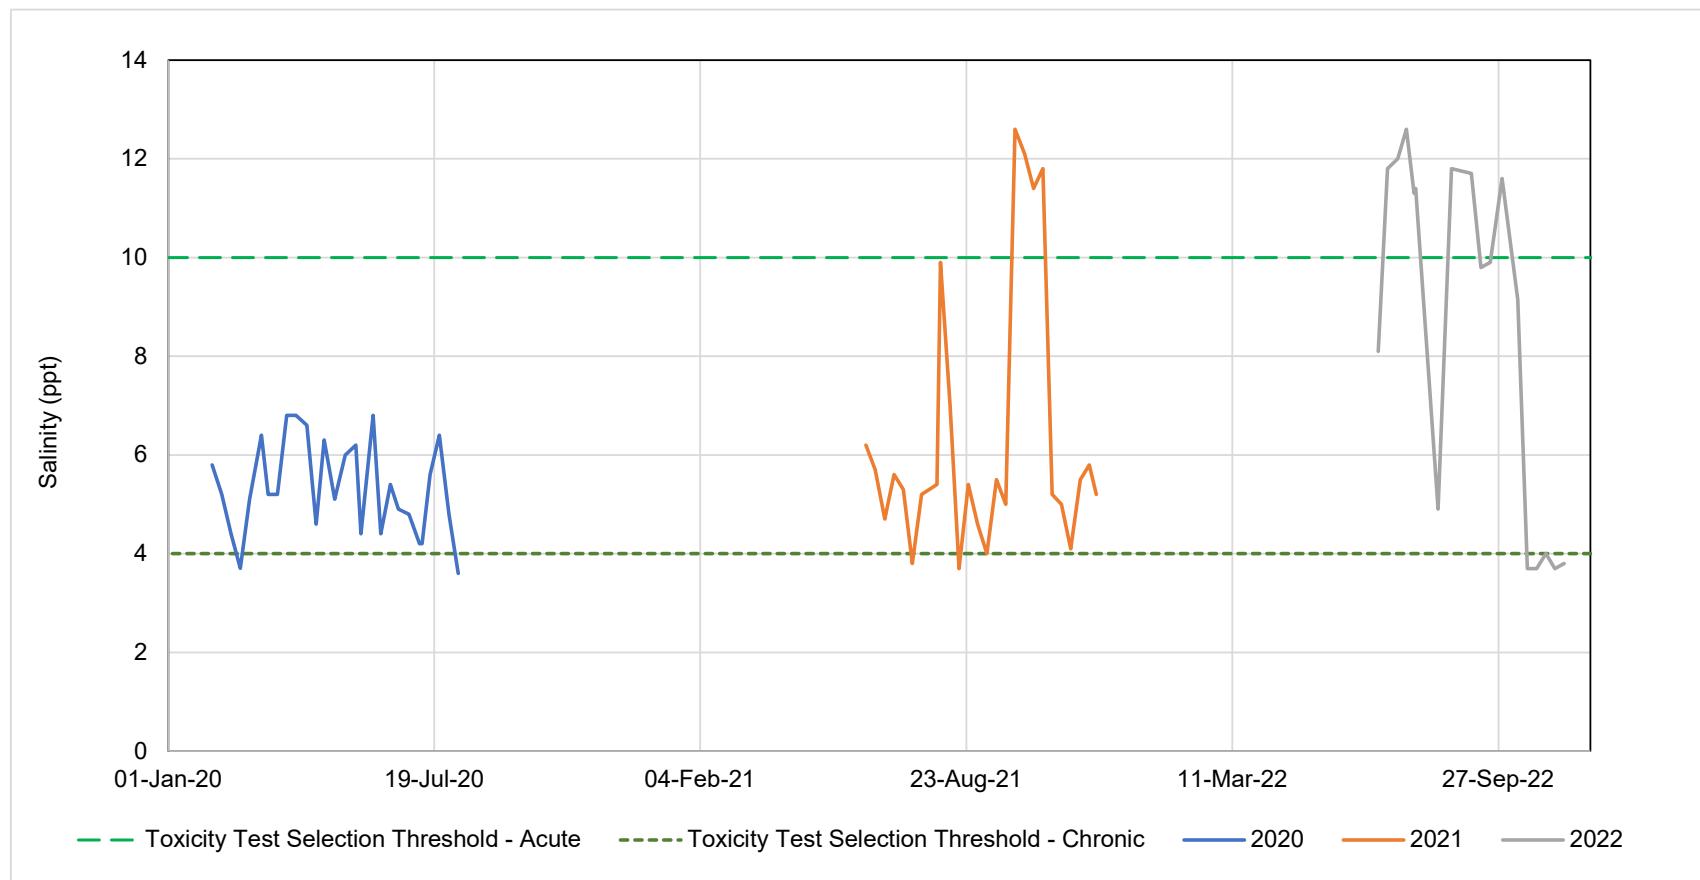

Figure 2.2: Salinity Concentrations of Hope Bay Mine Effluent (RBD1), 2020 to 2022

for 2020 through to 2022⁶. For all sublethal tests conducted, chronic toxicity test IC₂₅ (representing the concentration at which a 25% inhibition was observed relative to laboratory controls) was calculated from the corresponding survival, growth, or reproduction data. The IC₂₅ data were derived by the toxicity laboratory using non-linear regression models or linear interpolation models, as appropriate, aided by Comprehensive Environmental Toxicity Information System (CETIS) software (Tidepool Scientific Software, McKinleyville, CA). Effluent acute lethality and sublethal toxicity test results were reported to ECCC as part of quarterly/annual reporting requirements for the Hope Bay TIA effluent discharge and have been summarized for discussion in this Phase 1 EEM report.

Results of sublethal toxicity testing were evaluated relative to predicted effluent concentrations in the receiving environment, based on modelled results, to assess the potential for *in situ* effects to organisms living in Roberts Bay.

2.3 Receiving Environment Water Quality

2.3.1 Sampling Locations and Frequency

Based on modelling results, effluent exposed water quality monitoring in Roberts Bay focused on the area in the immediate vicinity of the effluent discharge diffuser (Figure 2.1). Three samples were collected corresponding to near surface, trapping depth, and near bottom. However, as conditions during sampling varied from year to year due to diffuser location and configuration, sampling depth corresponding to the trapping depth fluctuated over time, and near surface and near bottom depths varied based on change in location. Samples were collected at similar depths on the same day at the reference station located on the east side of Roberts Bay (Figure 2.1). The distance from shore and depth for the reference station were similar to the conditions near the diffuser.

Under MDMER, water quality monitoring is required four times per year at least one month apart, while the mine is depositing effluent (Schedule 4, Section 7(2)). However, as mentioned previously, Roberts Bay remains ice covered during a large portion of the year, with ice-out occurring in late June or early July, and ice cover returning in late September or early October. Water quality sampling in Roberts Bay commenced as soon as conditions were safe following ice-out, with subsequent samples collected a minimum of one month apart. As a result, only a maximum of three sampling events occurred during the ice-free periods for each year. Three sampling events occurred in 2020 and 2021, and only two sampling events occurred in 2022. Water quality monitoring results were reported annually by March 31 of the following

⁶ Only one sublethal toxicity sample was collected in 2020 due to the maintenance and repair issues with the submerged discharge line.

year to the Regulatory Information Submission System (RISS; per MDMER Schedule 5, Section 8).

2.3.2 Sample Collection and Analysis

At each sampling location, *in situ* water quality measurements were recorded using water collected from a Beta Bottle (used to collect the water sample) corresponding to each sample depth. Measurements included temperature (°C), dissolved oxygen (% and mg/L), pH, specific conductance ($\mu\text{S}/\text{cm}$), and salinity (ppt) using a calibrated water quality meter. Water samples at both the effluent-exposed and reference stations were collected using a beta bottle sampled at each of three depths at each station. Collecting samples at multiple depths helped to characterize conditions within the receiving environment, as well as aid in validating effluent mixing predictions. Quality control procedures associated with the sampling events included the collection of one duplicate sample and the submission of field and travel blank samples. Water samples were shipped to ALS Laboratories in Edmonton, Alberta, or Vancouver, British Columbia for analysis. Analyses included MDMER required substances, including metals, anions, and nutrients.

Receiving environment water quality was evaluated relative to guidelines protective of aquatic life, between effluent-exposed and reference sampling areas, and among depths. Water quality guidelines used for the EEM study included the CCME (Canadian Council of Ministers of the Environment) Canadian Water Quality Guidelines (CWQG, chronic and acute marine values; CCME 2022, including updates). Water chemistry data were summarized using annual means, with results assessed using the magnitude of difference between areas (i.e., exposed concentration divided by reference concentration).

3 EFFLUENT CHARACTERIZATION

3.1 Effluent Volume

Effluent from the Hope Bay Doris WTP and TIA (Station RBD1) was discharged at an average rate of approximately 6,150 m³/day in 2020, 5,980 m³/day in 2021, and 2,200 m³/day in 2022 (Figure 3.1). The total monthly volume of effluent discharged ranged from 4,504 to 225,270 m³ during the 2020 to 2022 period (Appendix Table B.1). Monthly discharge rates were generally comparable between 2020 and 2021, however, effluent was discharged at lower rates for most of 2022 (Figure 3.1). Lower rates of discharge in 2022 were due to recurring issues with toxicity to *Acartia tonsa* during pre-discharge toxicity testing, which prevented the mine from discharging effluent from the TIA. For those days in which effluent was discharged, total daily volume deposited ranged between 699 to 7,169 m³ in 2020, 12 to 8,922 m³ in 2021, and 4 to 5,877 m³ in 2022 (Appendix Table B.1). Intermittent low volumes of discharge occurred from the underground mine workings or during maintenance and testing procedures, but overall discharge to Roberts Bay was mainly sourced from the TIA, representing an average proportion of approximately 85% of effluent (Minnow 2021a,b). The cumulative volume of effluent discharged annually from the Doris Mine WTP and TIA at Station RBD1 in 2020 to 2022 ranged between 314,203 to 1,286,399 m³ (Appendix Table B.1).

3.2 Effluent Quality

Final effluent at Station RBD1 met all MDMER monthly mean and grab sample concentration limits (Table 3.1; Appendix Tables B.2 to B.4). Effluent characterization indicated that annual mean and grab sample mercury and selenium concentrations in effluent throughout the Phase 1 EEM period were well below the triggers for fish tissue monitoring (Tables 1.1 and 3.1; Appendix Tables B.2 to B.4). Effluent acute toxicity testing showed no toxicity to rainbow trout (2020 to 2022), threespine stickleback (2021 to 2022), or the copepod *Acartia tonsa* (2022) during the Phase 1 EEM period (Table 3.2).

Although effluent is not required to meet water quality guidelines, concentrations were evaluated to identify parameters that could potentially be used as an indicators within the receiving environment. Chromium and phosphorous were the only parameters with annual mean and maximum concentrations (all years for phosphorous; 2021 and 2022 for chromium) that exceeded an acute or chronic toxicity guideline (Table 3.1; Appendix Tables B.2 to B.4). Annual mean and maximum concentrations for all other parameters were below acute and chronic toxicity CWQG (Table 3.1; Appendix Tables B.2 to B.4).

3.3 Sublethal Toxicity

Sublethal toxicity testing of RBD1 effluent was conducted once in 2020 and twice in both 2021 and 2022. During each of these tests, no effects were observed to Pacific Topsmeat (*Atherinops affinis*) survival or growth or to sea urchin (*Strongylocentrotus purpuratus*) fertilization (Table 3.3). Effects to giant kelp (*Macrocystis pyrifera*) were observed during tests conducted in 2020 and 2021 but not during those conducted in 2022 (Table 3.3). Effect concentrations measured in 2020 (2.8% and 10.4% for germination and tube length, respectively) were lower than those observed in 2021 (Table 3.3).

3.3.1 Effluent Mixing In Roberts Bay

Under the original discharge configuration (40 m depth in 2020), modelling showed that effluent mixed rapidly in Roberts Bay, and the effluent plume would be buoyant in both open water and ice-covered conditions. The plume would be trapped 28.3 to 35.7 m below the surface of Roberts Bay, roughly 11.7 to 4.3 m above the diffuser, with horizontal boundaries of the plume ranging from 5.8 m to 14.8 m (ERM, 2016a,b). Rapid dilution to low concentrations (0.62% to 0.18%) were observed within the vertical (trapping depth) and horizontal plume boundaries for each of the open water and ice covered scenarios (ERM, 2016a,b). Modelled conditions indicated that effluent would be diluted to <1% within 8.7 m of the diffuser under worst case, under-ice conditions (ERM 2016a,b).

For the End of Pipe discharge configuration (20 m depth in 2021), the effluent plume was predicted to rise vertically in the water column for both open water and ice-covered conditions (Minnow 2021a). Due to the density of the effluent, and depending on seasonal conditions, the effluent plume would impinge at different water depths before spreading out horizontally. During ice-covered conditions, the plume was predicted to rise to the underside of the ice cover, while in open water conditions, it was predicted to be impinged at an intermediate water depth between 9 m and 13 m before spreading horizontally. Under these conditions effluent would be diluted to 2.8% within 9 m of the outfall during ice-covered conditions and 4.3% within 13 m of the outfall during open-water conditions. Under average open-water conditions, effluent was predicted to be diluted 1.8% within 30 m of the discharge and the 1% effluent plume could extend to 208 m (Minnow 2021a).

Modelled results of the installation of the diffuser at 20 m depth predicted effluent would rise in the water column and greater dilution of effluent would occur (Minnow 2021b). Under all discharge scenarios modelled with the diffuser located at 20 m depth, effluent would be diluted to less than 3% within 14 m of the discharge. Beyond this distance, further dilution is influenced by effluent salinity, discharge rate, season, and ambient currents in Roberts Bay (Minnow 2021b).

^a IC25 refers to the effluent concentration at which a 25% inhibition/reduction in endpoint was observed for test organisms relative to control.

^b IC50 refers to the effluent concentration at which a 50% inhibition/reduction in endpoint was observed for test organisms relative to control.

^c LC25 refers to the effluent concentration that resulted in 25% mortality of test organisms.

The maximum effluent concentration predicted 100 m from the diffuser was 1.25%, reaching 1% 151 m from the diffuser, based on average effluent salinity and conservative conditions in Roberts Bay (Minnow 2021b).

3.4 Predicted Receiving Environment Influence

Sublethal toxicity testing results indicated that effects were observed at low effluent concentrations for giant kelp in 2020 (2.8%) although recent tests have indicated no effect (Table 3.3). Effluent within Roberts Bay is diluted rapidly (i.e., effluent dilution of 4.3% within 13 m of the outfall for the End of Pipe configuration). Therefore, the spatial extent of effluent concentrations within Roberts Bay where effects could be observed would be very small and would be unlikely to cause any harm to aquatic life. Additionally, all discharge configurations indicate that effluent would be impinged at a trapping depth during the open water season, not exposing the more biologically productive surface layer (to 10 m depth) or the sediment-water interface to influence of effluent.

4 RECEIVING ENVIRONMENT WATER QUALITY

4.1 Water Chemistry

Annual mean measurements of *in situ* water quality parameters collected at mid-depth were similar at the effluent-exposed station of Roberts Bay and the reference station (Table 4.1). Sample depths changed across years due to the relocation of the diffuser, influencing temperature, conductivity, and salinity. However dissolved oxygen and pH were more comparable among years despite the variation in depth (Table 4.1; Appendix Tables B.5 to B.12). Salinity and pH measurements met applicable CWQG protective of aquatic life.

Three water sampling events sampling events in Roberts Bay were completed in both 2020 and 2021 (July, August, September⁷; Appendix Tables B.5 to B.10) and two sampling events were completed in 2022 (August, September; Appendix Tables B.11 and B.12). Effluent indicators were identified in the study design based on a comparison of effluent quality to receiving environment reference water quality (Minnow 2021c), and included ammonia, copper and manganese, which had concentrations in effluent that were more than 100 times the concentration measured at the reference area. Based on mean annual concentrations in the receiving environment for these parameters, concentrations of copper were comparable between areas during each year, while manganese and ammonia were slightly elevated at the mid depth samples in 2021 (2-fold and 4-fold, respectively), but not in 2020 or 2022 (Table 4.1). Nitrate concentrations were also slightly elevated (2-fold) at the mid-depth in 2021 but not the other years (Table 4.1). While the slight elevations help indicate the presence of effluent, estimated percent effluent concentrations were still low when comparing the effluent-exposed area to the reference area of Roberts Bay (i.e., less than 1%; Table 4.2). Mean annual concentrations of all other parameters at the mid-depth sample point were nearly identical between effluent-exposed and reference stations for each year (Table 4.1), as were results for the surface and bottom samples (Appendix Tables B.5 to B.12).

Of nutrients and anions assessed, only phosphorous exceeded the CWQG in 2020 (Table 4.1), however, this occurred at both the effluent-exposed and reference areas. Elevated concentrations at both the effluent-exposed and reference areas suggest there are natural fluctuations in water quality within Roberts Bay, indicating that the source is not effluent related.

⁷ In September 2020, effluent was not being discharged into Roberts Bay due to maintenance, but a sample was collected to evaluate non-discharge conditions at the exposed site.

Table 4.2: Ammonia Concentrations and Percent Effluent Estimates at the Effluent-Exposed area of Roberts Bay at Trapping Depth, Hope Bay Mine EEM, 2021

Location ^a	Coordinates (UTM - NAD83, Zone 13W)	Ammonia Concentration		Percent Effluent Estimate	
		(mg/L)		Mean	Max
		Mean	Max		
Effluent	-	6.35	12.7	-	-
Reference	431940	0.0051	0.0099	-	-
	7564932				
Effluent-Exposed	433128	0.0196	0.0489	0.23%	0.31%
	7565717				

Note: "—" indicates not applicable/no data.

^a Effluent-exposed and reference water samples were collected at comparable depths in which models have shown effluent would be trapped.

5 SUMMARY AND RECOMMENDATIONS

5.1 Summary

Agnico Eagle Hope Bay Mine became subject to the Metal and Diamond Mining Effluent Regulations (MDMER) under the federal Fisheries Act, February 1st, 2020, when the mine began discharging effluent into Roberts Bay. The MDMER outline requirements for routine effluent and water quality monitoring, and if triggered biological monitoring, collectively referred to as Environmental Effects Monitoring (EEM) studies. In accordance with MDMER requirements, this interpretive report provided a summary of effluent and water quality monitoring data. This is the first EEM Interpretive Report (Phase 1) submitted for the Hope Bay Mine.

As part of the Phase 1 EEM, effluent quality, toxicity test results, and receiving environment water quality for the 2020 to 2022 period was assessed. Due to the limited spatial extent of the effluent plume in Roberts Bay, biological monitoring studies were not required under MDMER as part of EEM for the Hope Bay Project (i.e., effluent concentrations 100 and 250 m from the discharge were less than 1%).

Effluent quality met all MDMER monthly mean and grab sample concentration limits and showed no acute toxicity to test organisms. Sublethal toxicity testing results show that effects were observed to Giant Kelp in 2020 and 2021 but not in 2022. Based on the rapid dilution of effluent within Roberts Bay and the concentrations at which effects were observed during those years, the risk to aquatic life within the receiving environment is very low.

The influence of the Hope Bay Mine discharge (RBD1) on water quality of Roberts Bay is negligible. Mean concentrations of ammonia, nitrate, and manganese were slightly elevated at the effluent-exposed area compared to the reference area for mid-depth samples in 2021, indicative of the presence of effluent, however no discernable difference was present for other years for these parameters, or for any other parameters over the three years of sampling. Phosphorus mean annual concentrations exceeded CCME chronic Canadian Water Quality Guidelines (CWQG) during one sample year, however elevated concentrations were observed at both the effluent-exposed and reference areas, indicating a natural influence within Roberts Bay rather than a mine-related influence.

Overall, the influence of the Hope Bay Mine discharge on Roberts Bay is nearly undetectable. Effluent mixing occurs rapidly, resulting in a spatially limited effluent plume and very low concentrations of mine-indicator parameters in receiving environment samples. Based on this rapid mixing of effluent, no sublethal toxicity to test organisms during recent tests, and no impairment to water quality within the receiving environment, the Hope Bay Mine effluent discharge is not having an impact on aquatic life within Roberts Bay.

5.2 Recommendations

Based on the findings of the Hope Bay Mine Phase 1 Interpretive Report, the following recommendations have been identified for the Phase 2 EEM (to be completed in three years):

- Based on the prescribed frequency under the MDMER, continue with periodic monitoring for the federal EEM. This includes sampling for effluent quality, characterization, acute toxicity, and sublethal toxicity, and sampling the receiving environment at the effluent-exposed and reference stations in Roberts Bay.
- As per the MDMER, after three years sublethal toxicity testing, the mine shall identify the most sensitive test organism and subsequently conduct tests once per calendar quarter. Giant kelp (*Macrocystis pyrifera*) produced the lowest geometric mean during sublethal toxicity tests over the past three years, and is therefore recommended as the test species moving forward.
- Based on modeled results of the effluent dilution within Roberts Bay with the diffuser installed at 20 m depth, there are several conditions under which effluent concentrations could exceed 1% 100 m from the discharge⁸. Therefore, it is recommended that a control-impact benthic invertebrate study be implemented for the next EEM phase and future EEM phases to determine if effects from effluent are occurring to the benthic invertebrate community.
- The Study Design for the next phase of the EEM must be submitted to ECCC (Environment and Climate Change Canada) no later than six months prior to implementing the next study in 2025. The Interpretive Report for the Phase 2 EEM must be submitted to ECCC on or before February 1st 2026.

⁸ Effluent concentrations at 250 m are predicted to be < 1%.

Dear Nancy Duquet-Harvey:

Subject: Hope Bay Project 1st EEM Study Design – action items identified

Environment and Climate Change Canada (ECCC) has reviewed your “TMAC Resources Hope Bay Mine Phase 1 Environmental Effects Monitoring Program Study Design”, submitted January 27, 2021 and the addendum submitted March 18, 2021 . Our review took into account requirements of the *Metal and Diamond Mining Effluent Regulations* (MDMER) of the *Fisheries Act*, information in the EEM Technical Guidance Document as well as generally accepted standards of good scientific practice. This review is not a substitute for reading the MDMER and does not in any way supersede or modify the *Fisheries Act* or the MDMER. In the event of an inconsistency between this review and the Act and/or the MDMER, the Act and the Regulations prevail.

The compiled review comments are attached. Comments in bold indicate where further information is required to meet regulatory requirements. Your response should be submitted, as an addendum, to the Environmental Effects Monitoring Electronic Reporting (EEMER) system (<https://ec.ss.ec.gc.ca/>).

If you have any questions or concerns about the EEM program or if you wish to discuss the study design, please contact Regional Coordinator Erik Allen at 780-717-4884 or at erik.allen@ec.gc.ca. For questions regarding EEMER, please contact EEM-ESEE@ec.gc.ca.

Sincerely,

Margaret Fairbairn
A/ Regional Director

Review comments and recommendations on “TMAC Resources Hope Bay Mine Phase 1 Environmental Effects Monitoring Program Study Design”, January 2021 submission

The following comments and recommendations are based on the review of the report by members of a Technical Advisory Panel (TAP) consisting of representatives from Environment and Climate Change Canada (ECCC), Crown-Indigenous Relations and Northern Affairs Canada (CIRNAC) and Nunavut Water Board (NWB).

Action items

1. pp. 19, 25. CIRNAC. Parameters such as ammonia, copper, and manganese are reactive (i.e., non-conservative parameters) in the marine environment such as Roberts Bay and might be partially removed from the water column during the mixing of effluent and seawater, for example, by chemical reactions (e.g, adsorption, precipitation, coprecipitation) and settling of particles in the water column. Consequently, if these parameters are used as indicators to validate model predictions and quantify spatial extent of effluent mixing, it would result in a substantial under-estimation of the spatial extend of effluent mixing, depending on the relative reactivity of the parameters and the extend of particle settling in Roberts Bay.
 - a) Please either provide further justifications on applying non-conservative parameters such as ammonia, copper, and manganese as indicators for effluent mixing; or,
 - b) apply appropriate parameters as indicators to validate model prediction and/or quantify spatial extent of effluent mixing.
2. p. 30. ECCC. Your study design tentatively proposes a benthic invertebrate community study, subject to subsequent effluent modelling for the repaired diffuser configuration (repairs planned for August 2021). The proposal to conduct a benthic invertebrate study was based on effluent modelling for the temporary configuration (no diffuser), which began effluent discharge in April 2021. Modelling for the temporary configuration predicted an effluent concentration greater than 1% at 100 m, but less than 1% at 208 m from the discharge point. Your study design does not propose a fish population study, presumably based on the predicted effluent concentrations under the temporary configuration. Modelling results for the repaired configuration, submitted as an addendum to the study design in March 2021 (Table 2, Minnow 2021), predict that the 1% effluent plume could exceed 100 m, and in one scenario, may exceed 250 m from the diffuser.

Please note that the timeframe to evaluate effluent information, for the purpose of determining biological study requirements under Schedule 5, subsection 9(1), ends on the day before your study design was required to be submitted (subsection 9(3)). For the purposes of applying subsection 9(3), the day your study design was submitted (January 27, 2021) would be considered as the day the study design was required to be submitted. As a result, the timeframe to evaluate effluent information to determine biological monitoring requirements for your Phase 1 study is February 1, 2020 to January 26, 2021. Please also note that paragraphs 9(1)(a) and (b) specify that the *highest* effluent concentration within this timeframe is used to determine biological monitoring requirements.

Effluent information from the period after January 26, 2021, up until the day before the next study design (Phase 2) is required to be submitted, must be used to determine biological monitoring requirements for your Phase 2 study, in accordance with subsections 9(1) and 9(3).

Effluent modelling for the original diffuser configuration (2.2 km pipeline with diffuser), which deposited effluent from February 1, 2020 to mid-August 2020, predicted <1% effluent within 8.7 m of the diffuser, for worst case, under ice conditions (p. 22). Water sampling at the ‘effluent exposed

sampling area' indicated effluent concentrations of 0.04% and 0.13% in July and August 2020, respectively. Please address the following questions related to effluent deposit during the period of February 1, 2020 to January 26, 2021, and provide updates to your study design as needed, based on application of the effluent information from this period to determine any biological monitoring requirements under paragraphs 9(1)(a) and (b).

- a) Please provide more information on the location of the 'effluent exposed sampling area' sampled for water quality in July and August 2020. How far was the sampling area from the diffuser? Were samples collected at multiple depths?
 - b) Was effluent discharged during the period after mid-August 2020, when discharge was suspended for maintenance, to January 26, 2021? (see also comment #3)
 - c) Modelling results for the original diffuser configuration (2020 effluent deposit) predicted the extent of the 1% plume at <8.7 m from the diffuser, for worst-case conditions (lowest dilution), under ice. What is the predicted extent of the 1% plume under worst case conditions for open water? Based on the modelling and water quality sampling for the 2020 effluent discharge, is it possible that the highest concentration of effluent during a period of deposit between February 1, 2020 and January 26, 2021 exceeded 1% at 100 m or 250 m from the diffuser?
 - d) **For the period of effluent deposit between February 1, 2020 and January 26, 2021, please provide estimates of effluent concentration at 100 m and 250 m from the point at which effluent enters the exposure area, and any additional supporting information, in accordance with Schedule 5, subparagraph 10(a)(i).**
3. p. 12. NWB. It was stated that the discharge pipe had floated to the sea ice bottom and became entrapped in the ice. However it is unclear if discharge occurred while the pipe was in surface waters and above the density gradient, and if this was included in the plume modeling.

Recommendation: Clarify if discharge occurred while the pipe was in surface waters and above the halocline, and if this was included in the plume modeling.

Other items

4. p. 13. NWB. Effluent discharge is to the marine environment, and as such the EEM is exclusive to the marine environment. However, the freshwater environment may also be impacted from mining activities, such as seepage from water containment facilities, surface runoff, dust generation, water discharged to tundra, etc. For example, the document states that "a total of 322m³ of contact water was discharged from the Madrid North Contact Water Pond to the tundra," and although there are no water bodies directly impacted by this activity, freshwater environmental monitoring should be considered to confirm impacts are not occurring.

Recommendation: Provide discussion on any considerations for freshwater environmental monitoring.

5. p. 27. ECCC. Table 2.2 and Table B.1 (Appendix B) report salinity concentrations in mg/L; however, according to descriptions in the text and model inputs, the units for salinity should be ppt rather than mg/L (ppm). Please confirm the units of measurement for salinity values in these tables.
6. p. 30. CIRNAC. Although the predicted buoyancy of the effluent plume might suggest that benthic organisms would not be exposed directly to the effluent plume, this does not necessarily mean that there is no indirect impact. For example, chemical reactions (e.g. adsorption, precipitation, coprecipitation) in the effluent plume as a result of mixing of effluent and seawater and the settling of particles in the water column could result in the partial removal of certain chemicals from the water column to the sediments below, which would potentially affect benthic organisms.

- a) Please either further clarify the assessment that benthic organisms in bottom sediments would likely not be exposed to effluent; or
 - b) consider and include both direct and potential indirect effects of effluent in any proposed biological monitoring plans
7. ECCC. As of June 1, 2021, un-ionized ammonia is included in the list of prescribed deleterious substances in section 3 of the MDMER. As a result, un-ionized ammonia must be included in the parameters required for EEM water quality monitoring, in accordance with Schedule 5, paragraph 7(1)(d). Un-ionized ammonia may be calculated from total ammonia, pH and temperature, using the formulas provided in subsection 12(4) of the MDMER.

Re: Hope Bay Mine Phase 1 EEM Study Design Comments Response

Dear Ms. Duquet Harvey,

On March 31st, 2022, Environment and Climate Change Canada (ECCC) provided comments related to their review of the Phase 1 Environmental Effects Monitoring (EEM) study design for the Hope Bay Mine, which also included reviews by the Nunavut Water Board (NWB) and Crown-Indigenous Relations and Northern Affairs Canada (CIRNAC). The comments include requests for clarification and/or additional information to support the review and approval of the study design, and information for consideration within the EEM Interpretive Report. The following responses have been prepared to address the comments provided by ECCC.

Sincerely,

Minnow Environmental Inc.

A handwritten signature in black ink, appearing to read "Kevin Martens".

Kevin Martens, B.Sc., R.P.Bio

Senior Aquatic Ecologist

cc: Pierre Stecko, M.Sc., EP, R.P.Bio., Principal Aquatic Scientist

Action Item 1: CIRNAC – Non-Conservative Tracer Parameters

Response: Minnow acknowledges that the identified parameters may reflect non-conservative effluent tracer parameters upon mixing within Roberts Bay. Ideally, an effluent tracer should behave conservatively in the receiving environment, but also must be elevated in effluent relative to the receiving environment in order to be detectable. Effluent quality was compared to reference water quality to identify potential parameters that could be used as tracers within the receiving environment (Table 2.2 of the study design). Ammonia, copper, and manganese were the only three parameters with concentrations in effluent greater than 100 times those observed in the receiving environment, and therefore may possibly be detectable at the discharge location at a level that might approach 1%. Based on the rapid dilution that occurs, parameters with minimal difference between effluent and receiver quality would have no detectable difference even in close proximity to the diffuser. Effluent and receiving environment chemistry will be reevaluated in the future to determine if other parameters may be suitable for use as a tracer. The deep discharge location and saline environment conditions present difficult conditions for conducting field based confirmation of modelled results.

Action Item 2: ECCC – Effluent Mixing and Benthic Invertebrate Survey Trigger

Response: Minnow acknowledges that the period for determining benthic invertebrate and fish health studies reflects information up to the date of study design submission (for the first EEM) and the period between study design submissions (for subsequent EEMs), per the MDMER Schedule 5, subparagraph 9(3)(a).

Effluent discharge dates and volumes prior to submission of the EEM study design were provided in Figure 2.7 of the study design, with no discharge occurring after August 22, 2020 (through study design submission). The information is presented in tabular form in Table 1 attached to this response.

Receiving environment water quality monitoring was conducted according to the Water Quality Monitoring Plan that was submitted to ECCC in May 2020 (Minnow 2020; attached), and subsequently revised for the 2021 sampling following the relocation of the discharge (outlined in the study design; Minnow 2021). Sampling at the effluent exposed area is conducted at the effluent diffuser at depths of 2 m, 11 m, and 19 m. This location was selected based on the small effluent mixing zone and the challenges associated with maintaining position in Roberts Bay to collect samples at multiple depths and multiple locations. Samples are collected at the same depths at the reference station.

Predicted effluent concentrations for both under ice and open water conditions were presented in Table 2.3 of the EEM study design (also attached). Due to reduced vertical mixing during winter

months, the effluent concentration was predicted to be <1% within 8.7 m of the diffuser (118:1 dilution ratio), which represented the worst-case conditions for the under-ice condition. Conversely, during summer months, effluent would be diluted to <0.4% within 14.8 m of the diffuser (270:1 dilution ratio). Therefore, per MDMER Schedule 5, subparagraph 10(a)(i), effluent concentrations at 100 m and 250 m from the diffuser would be << 1%. This conclusion is supported by the estimates obtained through receiving environment water quality monitoring (i.e., 0.13% at the diffuser; Table 2.4). Based on the information presented herein and within the submitted study design, and application of MDMER Schedule 5, subparagraph 9(3)(a), the Hope Bay Mine is not required to conduct a benthic invertebrate survey during the Phase 1 EEM, and the benthic invertebrate sampling program outlined within the study design will not be completed in 2022 for the Phase 1 EEM.

Action Item 3: NWB – Floating Discharge Line and Effluent Discharge

Response: Effluent was not being discharged at the time when the discharge line floated to the surface or after the line was cut to remove trapped air and allow the line segments to fall back to the ocean floor. Dates of effluent discharge prior to submission of the EEM study design are provided in Table 1.

Action Item 4: NWB – Freshwater Environmental Monitoring

Response: Routine water quality monitoring is conducted by the Hope Bay Mine within the freshwater receiving environments adjacent to the mine as outlined in the Aquatics Effects Monitoring Plan (AEMP; TMAC 2018) that was developed in consultation with and approved by NWB, the Kitikmeot Inuit Association, the NIRB, ECCC, CIRNAC and DFO. The AEMP includes biological monitoring programs within adjacent waterbodies designed to assess the potential effects of Project activities on the freshwater environment, assess predictions of the Madrid-Boston FEIS (TMAC 2017), and comply with requirements set forth in the Project permitting and licensing processes (TMAC 2019). This reporting is submitted annually to the NWB and provided to ECCC for comments through the review process.

Action Item 5: ECCC – Salinity Units Error

Response: Minnow confirms that the units for salinity should be parts per thousand (ppt) and has corrected Appendix Table B.1 to reflect the proper units (attached).

Action Item 6: CIRNAC – Buoyant Effluent and Benthic Invertebrate Survey

Response: Minnow acknowledges that dissolution and settling can occur for some effluent constituents upon mixing within Roberts Bay. Following MDMER criteria, Hope Bay will conduct benthic invertebrate community and sediment quality sampling if or when required within the

immediate area surrounding the effluent discharge to assess potential effects associated with discharge of effluent to the Roberts Bay receiving environment.

Action Item 7: Un-Ionized Ammonia

Response: Hope Bay acknowledges the required analysis of un-ionized ammonia in effluent and the receiving environment and has been conducting this analysis since June 1, 2021.

 Mean concentration exceeds a CCME chronic marine value.

 Mean concentration exceeds a CCME acute marine value.

Notes: CCME = Canadian Council of Ministers of the Environment; " - " = no data available, "NRG" = no recommended guideline.

^a Canadian Council of Ministers of the Environment Guidelines (CCME 2017).

^b Narrative guideline: "Human activities should not cause the salinity (expressed as parts per thousand [%]) of marine and estuarine waters to fluctuate by more than 10% of the natural level expected at that time and depth. Interim Guideline" (CCME, 1996).

^c Narrative guideline: "Clear flow - Maximum increase of 25 mg/L from background levels for any short-term exposure (e.g., 24-h period). Maximum average increase of 5 mg/L from background levels for longer term exposures (e.g., inputs lasting between 24 h and 30 d). High flow - Maximum increase of 25 mg/L from background levels at any time when background levels are between 25 and 250 mg/L. Should not increase more than 10% of background levels when background is ≥ 250 mg/L" (CCME, 1999).

^d Narrative guideline: "In order to minimize the occurrence of hypoxic events, it is suggested that total phosphorus concentrations within the estuary not exceed 50 µg/L during the late summer-early fall period, a value that approximates the concentration representing the 25th percentile for conditions when dissolved oxygen saturation values are >50 %" (CCME, 2007). This guideline applies to nearshore estuary waters.

^e CCME guideline is for the hexavalent (Cr(VI)) form of Chromium in seawater

Technical Memo

Date: May 6, 2020

To: Oliver Curran, Vice President, Environmental Affairs, TMAC Resources

From: Kevin Martens, B.Sc., R.P.Bio., Minnow Environmental Inc.

Cc: Kim Connors, M.Sc., Minnow Environmental Inc.

RE: TMAC Hope Bay Project Water Quality Monitoring Plan

TMAC Resources (TMAC) Hope Bay Project is located within the Hope Bay greenstone belt, along the south shore of Melville Sound in the West Kitikmeot region of mainland Nunavut (Figure 1). The Hope Bay Project is situated on an 80 by 20 km property that encompasses three main gold deposits: Doris, Madrid, and Boston. The Doris gold deposit is the northernmost deposit and is actively mined by TMAC. The Madrid deposit is also located in the northern region of the property, just south of the Doris Mine. The Boston deposit is at the south end of the property, near Aimaokatalok Lake (Figure 1). Nearby communities include Cambridge Bay (Iqaluktutiaq), Bay Chimo (Umingmaktok), and Bathurst Inlet (Kingaok).

TMAC commenced discharging to Roberts Bay on February 1, 2020. Notification of the Final Discharge Point (FDP) was provided to Environment and Climate Change Canada on March 16, 2020, as required under Section 9 of the Metal and Diamond Mining Effluent Regulations (MDMER; Government of Canada 2018). This memo provides an overview of the effluent diffuser, the receiving environment into which effluent is discharged, and the water monitoring program to be implemented by TMAC to meet Section 7 of Schedule 5 in the MDMER.

Roberts Bay is a 1,430 hectare estuary on the south shore of Melville Sound, to the east of Hope Bay (Figure 1). Freshwater enters Roberts Bay from a number of tributaries, with the two largest being Little Roberts Outflow and Glenn Outflow. Water within Roberts Bay exchanges freely with the water in Melville Sound. Ice cover is present on Roberts Bay from late September or early October through late June, with open water present through the remaining months (ERM 2016a). During ice covered months, 1 to 2 m of ice forms on Roberts Bay, sheltering it from atmospheric winds and reducing circulation. Through warming, wind, and freshwater inputs during the open water season, circulation within the bay increases, resulting in a ten-fold increase in the exchange rate with Melville Sound (ERM 2016a). Tidal ebb and flow currents are weak within the bay. The

south and west shores of Roberts Bay are adjacent to infrastructure and activities associated with the Hope Bay Project (Figure 1).

Discharge from the Hope Bay Project will include saline groundwater from the underground workings (up to 25 ppt salinity) and freshwater from the Tailings Impoundment Area (0.2 ppt salinity; ERM 2016b). During discharge, effluent released will be either a combination of the two sources or one of the sources, depending on water management needs at the site. From the outfall berm, effluent is pumped and discharged to Roberts Bay through a single 2.2 km insulated pipeline to a multi-port diffuser located at a depth of 40 m and 575 m from the nearest shoreline (Figure 2). The diffuser is 95 m long and has 20 ports spaced at 5 m intervals that are 30 mm in diameter and is raised 0.6 m above the sea floor, discharging horizontally into Roberts Bay (Figure 3). Effluent salinity will fluctuate based on the source of water but is expected to be more buoyant than the receiving environment, and will therefore rise in the water column before becoming fully mixed at a trapping depth¹. Modelling results indicate effluent will be quickly diluted, with concentrations 15 m from the diffuser reaching effluent dilution ratios of 160:1 (0.6%) at trapping depth when the most saline and coldest groundwater is discharged under ice² (ERM 2016b). The predicted trapping depth will fluctuate based on effluent source and season, ranging from 28 to 35 m depth under ice, and 34 to 36 m during the open water season.

Based on modelling results, water quality monitoring in Roberts Bay will focus on the area in the immediate vicinity of the effluent discharge diffuser. Effluent-exposed water samples will be collected at one location mid-length along the diffuser (Figure 2). Three samples will be collected, corresponding to near surface (5 m depth), trapping depth (estimated to be 35 m depth), and near bottom (39 m depth). Prior to collecting the trapping depth sample, an *in situ* profile of conductivity and salinity will be conducted to determine the presence of the effluent plume, if possible. Collecting samples at multiple depths will characterize conditions within the receiving environment, as well as aid in validating effluent mixing predictions. Samples will be collected at a reference station on the same day located on the opposite side of Roberts Bay (Figure 2). The distance from shore and depth will be similar to the conditions near the diffuser (e.g., approximately 575 m from the shore, 40 m deep). Samples will be collected at the same depths as the effluent-exposed station (i.e., 5 m, 35 m, 39 m). This will allow for direct comparison of water quality at each depth. Quality control procedures associated with the sampling events will include the collection of one duplicate sample and the submission of field and travel blank samples. Water samples will be shipped to ALS Laboratories in Edmonton, Alberta for analysis. Analyses will include parameters shown in Table 1.

¹ The depth at which effluent will no longer rise in the water column after mixing.

² This represents worst-case conditions based on modelled effluent mixing scenarios.

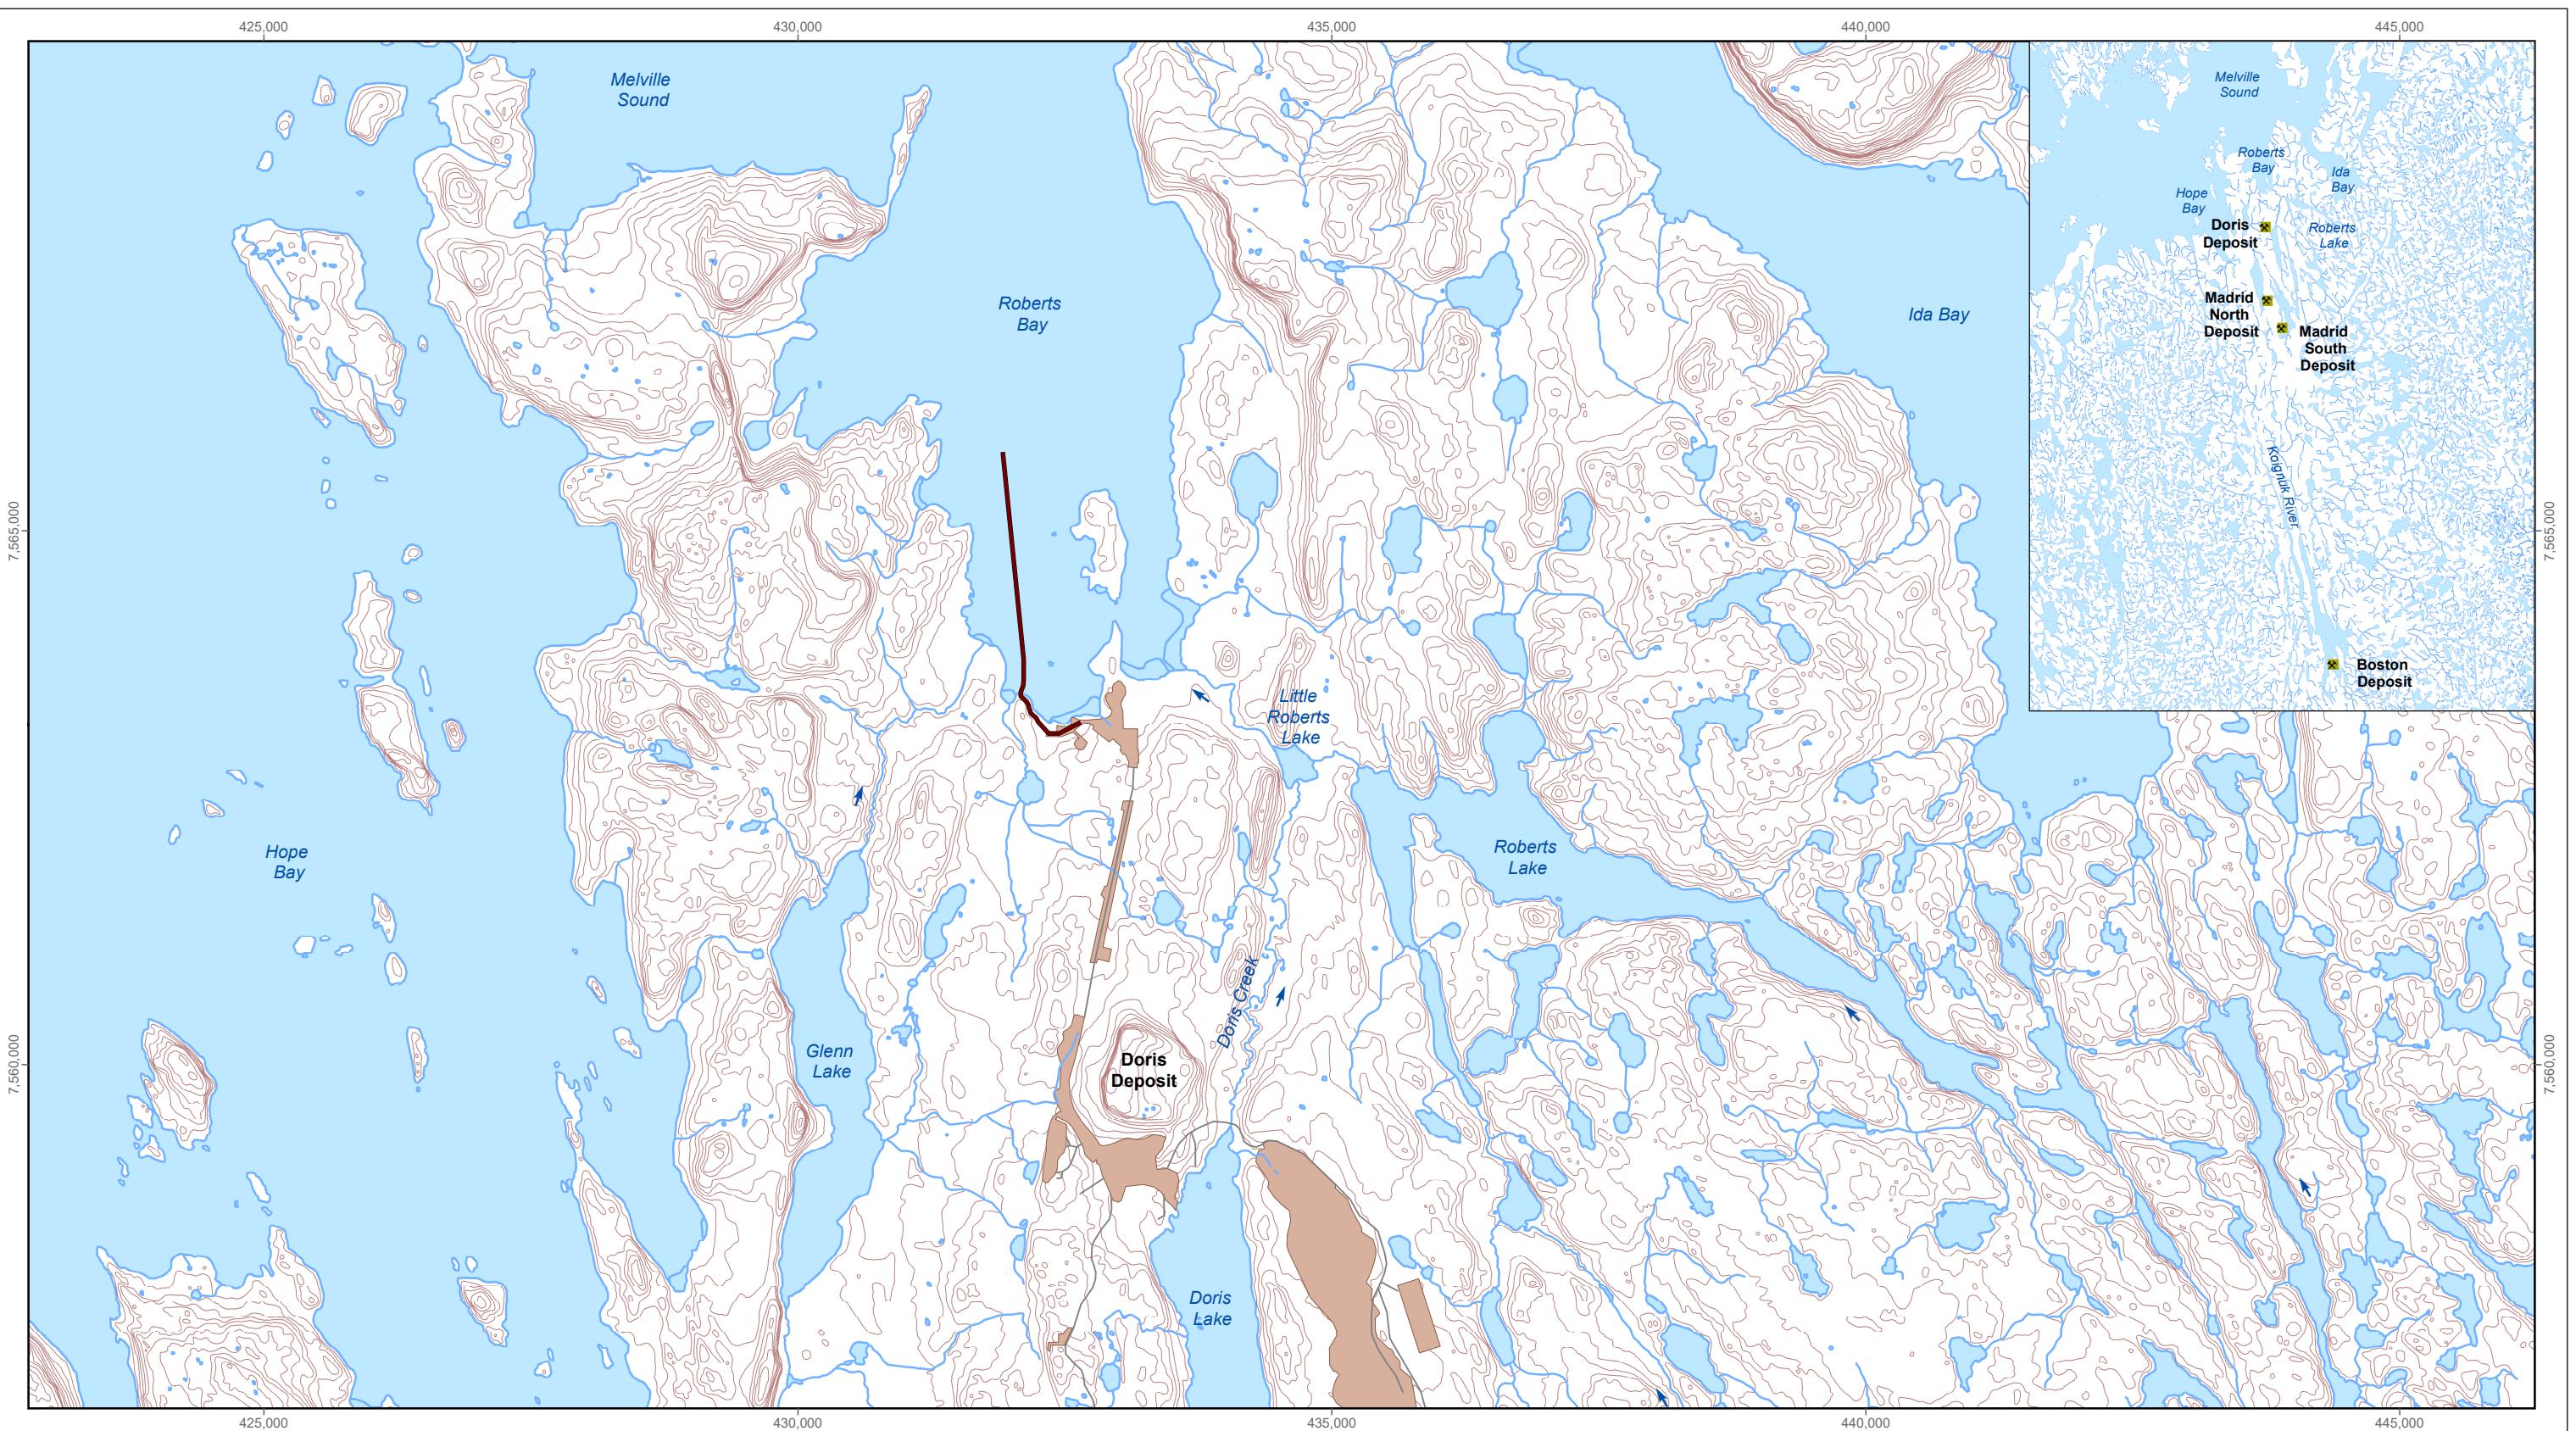

At each sampling location, *in-situ* water quality measurements will be recorded using water from the Beta Bottle (used to collect the water sample) corresponding to each sample. Measurements will include temperature (°C), dissolved oxygen (% and mg/L), pH, specific conductance ($\mu\text{S}/\text{cm}$), and salinity (ppt; Table 1) using a calibrated water quality meter.

Under MDMER, water quality monitoring is required four times per year at least one month apart, while the mine is depositing effluent (Schedule 4, Section 7(2)). However, as mentioned previously, Roberts Bay remains ice covered during a large portion of the year, with ice-out occurring in late June or early July, and ice cover returning in late September or early October. Water quality sampling in Roberts Bay will commence as soon as conditions are safe following ice-out, with subsequent samples collected a minimum of one month apart. As a result, it is anticipated that only three sampling events may occur during the ice-free period. If conditions remain safe, a fourth sampling event will occur prior to ice forming on the bay. Water quality monitoring results will be reported annually by March 31 of the following year to the Regulatory Information Submission System (RISS; per MDMER Schedule 5, Section 8).

Dear Nancy Duquet-Harvey:

Subject: Hope Bay Project 1st EEM Study Design

Environment and Climate Change Canada (ECCC) has reviewed your “TMAC Resources Hope Bay Mine Phase 1 Environmental Effects Monitoring Program Study Design”, submitted January 27, 2021 and the addenda submitted March 18, 2021 and May 17, 2022. Our review took into account requirements of the *Metal and Diamond Mining Effluent Regulations* (MDMER) of the *Fisheries Act*, information in the EEM Technical Guidance Document as well as generally accepted standards of good scientific practice. This review is not a substitute for reading the MDMER and does not in any way supersede or modify the *Fisheries Act* or the MDMER. In the event of an inconsistency between this review and the Act and/or the MDMER, the Act and the Regulations prevail.

A review comment for the mine to consider is attached. No further response to the review comment is required.

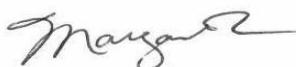

ECCC anticipates receiving your 1st interpretive report no later than February 1, 2023. Although you have not proposed biological monitoring studies, any applicable information required under Schedule 5, section 12 of the MDMER must be provided in the report (e.g., paragraphs 12(1)(o), (q) and (r)). Regulated facilities are required to

submit EEM reports to the Environmental Effects Monitoring Electronic Reporting system (EEMER) at <https://ec.ss.ec.gc.ca/>.

If you have any questions or concerns about the EEM program or if you wish to discuss the study design, please contact Regional Coordinator Erik Allen at 780-717-4884 or at erik.allen@ec.gc.ca. For questions regarding EEMER, please contact EEM-ESEE@ec.gc.ca.

Sincerely,

Margaret Fairbairn
A/ Regional Director

Review comment on “Hope Bay Mine Phase 1 EEM Study Design Comments Response”, May 2022 submission

The following comment is based on the review of the report by members of a Technical Advisory Panel (TAP) consisting of representatives from Environment and Climate Change Canada (ECCC), Crown-Indigenous Relations and Northern Affairs Canada (CIRNAC) and Nunavut Water Board (NWB).

1. CIRNAC. In your response you state: *“Minnow acknowledges that the identified parameters may reflect non-conservative effluent tracer parameters upon mixing within Roberts Bay. Ideally, an effluent tracer should behave conservatively in the receiving environment, but also must be elevated in effluent relative to the receiving environment in order to be detectable.”*

Please note that effective tracer parameters do not have to be elevated in the effluent relative to the receiving environment in order to be detectable. They only need to be sufficiently different in the effluent from the receiving environment, i.e., they can be either elevated or depleted in the effluent relative to the receiving environment in order to be detectable.

Table B.2: Hope Bay Effluent (RBD1) Quality Data, 2020

Notes: **Bold** - Concentration exceeds an average discharge criteria limit, following MDMER. CCME = Canadian Council of Ministers of the Environment. " - " = no data available. "NRC" = no recommended guideline.

^a Canadian Council of Ministers of the Environment Guidelines (CCME 2017)

^b Narrative guideline: "Human activities should not cause the salinity (expressed as parts per thousand [%]) of marine and estuarine waters to fluctuate by more than 10% of the natural level expected at that time and depth. Interim Guideline" (CCME, 1996).

^c Narrative guideline: "Clear flow - Maximum increase of 25 mg/L from background levels for any short- term exposure (e.g., 24-h period). Maximum average increase of 5 mg/L from background levels for longer term exposures (e.g., inputs lasting between 24 h and 30 d). High flow - Maximum increase of 25 mg/L from background levels at any time when background levels are between 25 and 250 mg/L. Should not increase more than 10% of background levels when background is ≥ 250 mg/L" (CCME, 1999).

^d Narrative guideline: "In order to minimize the occurrence of hypoxic events, it is suggested that total phosphorus concentrations within the estuary not exceed 50 µg/L during the late summer-early fall period, a value that approximates the concentration representing the 25th percentile for conditions when dissolved oxygen saturation values are >50 %" (CCME, 2007). This guideline applies to nearshore estuary waters.

^e CCME guideline is for the hexavalent (Cr(VI)) form of Chromium in seawater.

Table B.3: Hope Bay Effluent (RBD1) Quality Data, 2021

Notes: **Bold** - Concentration exceeds an average discharge criteria limit, following MDMER. CCME = Canadian Council of Ministers of the Environment. " - " = no data available. "NRG" = no recommended guideline.

^a Canadian Council of Ministers of the Environment Guidelines (CCME 2017).

^b Narrative guideline: "Human activities should not cause the salinity (expressed as parts per thousand [%]) of marine and estuarine waters to fluctuate by more than 10% of the natural level expected at that time and depth. Interim Guideline" (CCME, 1996)

^c Narrative guideline: "Clear flow - Maximum increase of 25 mg/L from background levels for any short-term exposure (e.g., 24-h period). Maximum average increase of 5 mg/L from background levels for longer term exposures (e.g., inputs lasting between 24 h and 30 d). High flow - Maximum increase of 25 mg/L from background levels at any time when background levels are between 25 and 250 mg/L. Should not increase more than 10% of background levels when background is $\geq 250 \text{ mol/L}$ " (CCME, 1999).

^d Narrative guideline: "In order to minimize the occurrence of hypoxic events, it is suggested that total phosphorus concentrations within the estuary not exceed 50 µg/L during the late summer-early fall period, a value that approximates the concentration representing the 25th percentile for conditions when dissolved oxygen saturation values are >50 %" (CCME, 2007). This guideline applies to

^a COMC guidelines for the assessment (Q/M) of chemical substances.

^e CCME guideline is for the hexavalent (Cr(VI)) form of Chromium in fresh water and marine environments (SCD/2000-002).

Notes: **Bold** - Concentration exceeds an average discharge criteria limit, following MDMER. CCME = Canadian Council of Ministers of the Environment. " - " = no data available. "NRG" = no recommended guideline.

^a Canadian Council of Ministers of the Environment Guidelines (CCME 2017).

^b Narrative guideline: "Human activities should not cause the salinity (expressed as parts per thousand [%]) of marine and estuarine waters to fluctuate by more than 10% of the natural level expected at that time and depth. Interim Guideline" (CCME, 1996).

^c Narrative guideline: "Clear flow - Maximum increase of 25 mg/L from background levels for any short-term exposure (e.g., 24-h period). Maximum average increase of 5 mg/L from background levels for longer term exposures (e.g., inputs lasting between 24 h and 30 d). High flow - Maximum increase of 25 mg/L from background levels at any time when background levels are between 25 and 250 mg/L. Should not increase more than 10% of background levels when background is ≥ 250 mg/L" (CCME, 1999).

^d Narrative guideline: "In order to minimize the occurrence of hypoxic events, it is suggested that total

Notes: **Bold** - Concentration exceeds an average discharge criteria limit, following MDMER. CCME = Canadian Council of Ministers of the Environment. " - " = no data available. "NRG" = no recommended guideline.

^a Canadian Council of Ministers of the Environment Guidelines (CCME 2017).

^b Narrative guideline: "Human activities should not cause the salinity (expressed as parts per thousand [%]) of marine and estuarine waters to fluctuate by more than 10% of the natural level expected at that time and depth. Interim Guideline" (CCME, 1996).

^c Narrative guideline: "Clear flow - Maximum increase of 25 mg/L from background levels for any short-term exposure (e.g., 24-h period). Maximum average increase of 5 mg/L from background levels for longer term exposures (e.g., inputs lasting between 24 h and 30 d). High flow - Maximum increase of 25 mg/L from background levels at any time when background levels are between 25 and 250 mg/L. Should not increase more than 10% of background levels when background is ≥ 250 mg/L" (CCME, 1999).

^d Narrative guideline: "In order to minimize the occurrence of hypoxic events, it is suggested that total phosphorus concentrations within the estuary not exceed 50 µg/L during the late summer-early fall

Table B.5: Water Quality Data from Reference and Exposed Stations, Roberts Bay, July 15, 2020

■ Mammals | Fishes | Insects | Crustaceans | Oligochaetes | Annelids | Molluscs | Ciliates | Protozoa | Fungi | Bacteria

Mean concentration exceeds a CCME chronic marine value

Mean concentration exceeds a CCME acute marine value.
Notes: **Bold** - Concentration exceeds an average discharge criteria limit, following MDMER. CCME = Canadian Council of Ministers of the Environment. " - " = no data available. "NRG" = no recommended guideline.

^a Canadian Council of Ministers of the Environment Guidelines (CCME 2017)

^b Canadian Council of Ministers of the Environment Guidelines (CCME 2017).

^c Narrative guideline: "Clear flow - Maximum increase of 25 mg/L from background levels for any short-term exposure (e.g., 24-h period). Maximum average increase of 5 mg/L from background levels for longer term exposures (e.g., inputs lasting between 24 h and 30 d). High flow - Maximum increase of 25 mg/L from background levels at any time when background levels are between 25 and 250 mg/L. Should not increase more than 10% of background levels when background is ≥ 250 mg/L" (CCM^E, 1999).

^d Narrative guideline: "In order to minimize the occurrence of hypoxic events, it is suggested that total phosphorus concentrations within the estuary not exceed 50 µg/L during the late summer-early fall period, a value that approximates the concentration representing the 25th percentile for conditions when dissolved oxygen saturation values are >50 %" (CCME 2007). This guideline applies to nearshore estuarine waters.

^e CCME guideline is for the hexavalent (Cr(VI)) form of Chromium in seawater.

Table B.7: Water Quality Data from Reference and Exposed Stations, Roberts Bay, September 22, 2020

Mean concentration exceeds a CCME chronic marine value.

Mean concentration exceeds a CCME chronic marine value
Mean concentration exceeds a CCME acute marine value

Mean concentration exceeds a CCME acute marine value.
Notes: **Bold** - Concentration exceeds an average discharge criteria limit following MDMER. CCME = Canadian Council of Ministers of the Environment. " - " = no data available. "NRG" = no recommended guideline.

^a Canadian Council of Ministers of the Environment Guidelines (CCME 2017)

^b Narrative guideline: "Human activities should not cause the salinity (expressed as parts per thousand [%]) of marine and estuarine waters to fluctuate by more than 10% of the natural level expected at that time and depth. Interim Guideline" (CCME, 1996).

^c Narrative guideline: "Clear flow - Maximum increase of 25 mg/L from background levels for any short-term exposure (e.g., 24-h period). Maximum average increase of 5 mg/L from background levels for longer term exposures (e.g., inputs lasting between 24 h and 30 d). High flow - Maximum increase of 25 mg/L from background levels at any time when background levels are between 25 and 250 mg/L. Should not increase more than 10% of background levels when background is > 250 mg/L" (OCM-1, 1999).

^d Narrative guideline: "In order to minimize the occurrence of hypoxic events, it is suggested that total phosphorus concentrations within the estuary not exceed 50 µg/L during the late summer-early fall period, a value that approximates the concentration representing the 25th percentile for conditions when dissolved oxygen saturation values are >50 %" (CCME, 2007). This guideline applies to

⁶ COME guidelines for the hexavalent ($\text{Cr}(\text{VI})$) form of Chromium in nearshore estuary waters.

Table B.9: Water Quality Data from Reference and Exposed Stations, Roberts Bay, August 21, 2021

Mean concentration exceeds a CCME chronic marine value.

Mean concentration exceeds a CCME chronic marine value

Mean concentration exceeds a CCME acute marine value.
Notes: **Bold** - Concentration exceeds an average discharge criteria limit following MDMER. CCME = Canadian Council of Ministers of the Environment. " - " = no data available. "NRG" = no recommended guideline.

^a Canadian Council of Ministers of the Environment Guidelines (CCME 2017).

^b Narrative guideline: "Human activities should not cause the salinity (expressed as parts per thousand [%]) of marine and estuarine waters to fluctuate by more than 10% of the natural level expected at that time and depth. Interim Guideline" (CCME, 1996).

^c Narrative guideline: "Clear flow - Maximum increase of 25 mg/L from background levels for any short-term exposure (e.g., 24-h period). Maximum average increase of 5 mg/L from background levels for longer term exposures (e.g., inputs lasting between 24 h and 30 d). High flow - Maximum increase of 25 mg/L from background levels at any time when background levels are between 25 and 250 mg/L. Should not increase more than 10% of background levels when background is > 250 mg/L" (CCME, 1999).

^d Narrative guideline: "In order to minimize the occurrence of hypoxic events, it is suggested that total phosphorus concentrations within the estuary not exceed 50 µg/L during the late summer-early fall period, a value that approximates the concentration representing the 25th percentile for conditions when dissolved oxygen saturation values are >50 %" (CCME, 2007). This

^e CCME guideline is for the hexavalent (Cr(VI)) form of Chromium in seawater

 Values did not meet the data quality objective of ≤ 25% relative percent difference.

Note: "-" indicates no data.

^a The method detection limit (MDL) value was used in instances where values less than the MDL were reported.

Table B.16: Water Quality Data from Field, Travel, and Equipment Blanks, Robert's Bay, Robert's Bay, 2020

Mean concentration exceeds a CCME chronic marine value

Mean concentration exceeds a CCME chronic marine value.
Mean concentration exceeds a CCME acute marine value.

Notes: CCME = Canadian Council of Ministers of the Environment. " - " = no data available. "NRG" = no recommended guideline.

^a Canadian Council of Ministers of the Environment Guidelines (CCME 2017).

^b Narrative guideline: "Human activities should not cause the salinity (expressed as parts per thousand [%]) of marine and estuarine waters to fluctuate by more than 10% of the natural level expected at that time and depth. Interim Guideline" (CCME, 1996).

^c Narrative guideline: "Clear flow - Maximum increase of 25 mg/L from background levels for any short-term exposure (e.g., 24-h period). Maximum average increase of 5 mg/L from background levels for longer term exposures (e.g., inputs lasting between 24 h and 30 d). High flow - Maximum increase of 25 mg/L from background levels at any time when background levels are between 25 and 250 mg/L. Should not increase more than 10% of background levels when background is > 250 mg/L" (CCME, 1999).

^d Narrative guideline: "In order to minimize the occurrence of hypoxic events, it is suggested that total phosphorus concentrations within the estuary not exceed 50 µg/L during the late summer-early fall period, a value that approximates the concentration representing the 25th percentile for conditions when dissolved oxygen saturation values are >50 %" (CCME, 2007). This guideline applies to nearshore

estuary waters.

 Mean concentration exceeds a CCME chronic marine value.

 Mean concentration exceeds a CCME acute marine value.

Notes: CCME = Canadian Council of Ministers of the Environment. " - " = no data available. "NRG" = no recommended guideline.

^a Canadian Council of Ministers of the Environment Guidelines (CCME 2017).

^b Narrative guideline: "Human activities should not cause the salinity (expressed as parts per thousand [%]) of marine and estuarine waters to fluctuate by more than 10% of the natural level expected at that time and depth. Interim Guideline" (CCME, 1996).

^c Narrative guideline: "Clear flow - Maximum increase of 25 mg/L from background levels for any short-term exposure (e.g., 24-h period). Maximum average increase of 5 mg/L from background levels for longer term exposures (e.g., inputs lasting between 24 h and 30 d). High flow - Maximum increase of 25 mg/L from background levels at any time when background levels are between 25 and 250 mg/L. Should not increase more than 10% of background levels when background is ≥ 250 mg/L" (CCME, 1999).

^d Narrative guideline: "In order to minimize the occurrence of hypoxic events, it is suggested that total phosphorus concentrations within the estuary not exceed 50 µg/L during the late summer-early fall period, a value that approximates the concentration representing the 25
